In 1638, having obtained his father's consent to improve himself by foreign travel, Milton set out for the continent. At Paris he was received with distinction by lord Scudamore, the ambassador from England, by whom he was introduced to the notice of the illustrious Grotius, who then resided in the French capital, as the minister of Christina, the queen of Sweden. After the delay of a few days at Paris, he renewed his progress, and pursued the direct road to Nice, where a vessel received and landed him at Genoa. From this city he passed immediately through Leghorn and Pisa to Florence, and on the banks of the Arno he made what may be regarded as his first pause. Here he resided two months, and by the brilliancy of his conversation, and mildness of his manners, made himself the object of very general admiration. Here he obtained admission into those private academies, which had been instituted by the Medici for the advancement of literature, and for the cementing of friendships among its votaries. The English bard could in this place enumerate in the list of his friends all the great, the respectable, and deeply learned men of Italy, who appear to have been lost in surprise at the spectacle, presented to them, of a native of Britain, a country just emerging, as they imagined, from barbarism, who to an acquaintance, not superficial, with all the sciences, united a profound knowledge of classical and Italian letters; whose mind was at once sublime and deep, accurate and comprehensive, powerful and acute; patient to follow judgment in the gradual investigation of philosophical truth, yet delighted to fly with the more aerial offspring of the brain on the high and expatiating wing of imagination. During this visit to Florence he saw and conversed with the great Galileo, that memorable victim of priestley ignorance and superstition. "There it was," says Milton, "that I found and visited the famous Galileo, grown old, a prisoner to the Inquisition, for thinking in astronomy otherwise than the Franciscan and Dominican licensers thought." On his leaving Florence, our traveller proceeded through Sienna to Rome, and then visited Naples, where he was kindly received by Manso, marquis of Villa. At Rome he was introduced, by Holstenius, the learned keeper of the Vatican library, to the attentions of cardinal Barberini, who at that time possessed the whole delegated sovereignty of Rome under his uncle, Urban VIII. At a great musical entertainment which the cardinal gave, he looked for our traveller among the crowd at the door, and brought him, almost by the hand, into the assembly. It is supposed, that it was at this concert Milton was first struck with the charms and the inimitable voice of Leonora Baroni, which had been made the general theme of their praise by the contemporary poets of Italy: and she is probably the person who has been celebrated by Milton in her own language, and who was the object of his love in his Italian sonnets.

At Naples the attentions paid to Milton were of the most flattering nature; the marquis of Villa not only conducted him through the viceroy's palace, and to a sight of all that was worthy to be shewn in the city, but honoured him also with some familiar and very friendly visits. The imprudent freedom, with which Milton had discovered his sentiments on the subject of religion, was the only circumstance which deprived him of a still more unreserved intercourse with this elegant and accomplished nobleman. Having completed his intended residence at Naples, he began to make preparations for the execution of the remaining part of his plan of travel, which extended to Sicily and Greece; but while he was engaged in this business he received letters from England, acquainting him with the distracted state of his country, and with the near prospect of a civil war; he determined to return. "As I was desirous," he says, "to pass into Sicily and Greece, the melancholy intelligence from England of the civil war recalled me; for I esteemed it dishonourable for me to be lingering abroad, even for the improvement of my mind, when my fellow-citizens were contending for their liberty at home." He, however, resolved to revisit Rome, where he remained two months; and whenever his religion was attacked, he scrupled not to vindicate its principles with spirit and ardour, even within the precincts of the sacerdotal palace. From Rome he went to Florence, and his second visit to this city, which the kindness of his friends made a species of home to him, was of equal duration with his first. When he departed from Florence, he crossed the Apennines, and travelled through Bologna and Ferrara to Venice. He spent a month in viewing the curiosities of this celebrated city, and then pursued his returning course through Verona and Milan, over the Alps, and by lake Lemanus to Geneva. Here he contracted an acquaintance with two learned divines, John Diodati and Frederic Spanheim. He now returned through France to England, having been absent about fifteen months. On his arrival he found the civil commotions of his country hastening to a crisis, and as he had expressed impatience to be present on the theatre of these disputes, it has been thought extraordinary that he did not instantly take upon himself some active part. But his tastes and habits were altogether literary, and he had been long pondering upon some subject of English poetry worthy of his genius, and capable of being made a passport to the immortality to which he aspired. For the present, therefore, he fixed himself in the metropolis, undertook the education of his sister's sons, of the name of Philips. Shortly after he was applied to by several parents to admit their children to the benefit of his tuition, to which he assented, and by this means he has exposed himself to the title of school-master, which his enemies, and the enemies of human happiness and intellectual improvement, who employed it as a term of reproach, conceived to be of a nature to degrade him. He took a house in a garden in Aldersgate-street, and opened an academy for board and education. Here, in his little circle of scholars, he was usefully, if not splendidly, engaged; and he could not perhaps conceive, while he was essentially promoting the highest interests of some of his species, that he was degrading himself in the estimation of the rest. In his conduct to his pupils, he was familiar and free where he could be so, and was never rigid but by compulsion. His form of instruction respected things more than words, and attempted to communicate knowledge when the understanding was, perhaps, incapable of receiving more than the key which opened the important gate. Instead of the common classics, he put into the hands of his scholars such Latin and Greek authors as treated on the arts and sciences, and philosophy. These were ill calculated to render learning pleasant to beginners, and from the imperfect state of ancient science, such a course was as likely to inculcate error as truth. He performed the

duties

duties of inftruction with great affiduity, and fet the example of hard ftudy and fpare diet to his pupils, whom he feems, in fome refpects, to have difciplined with the feverity of old times.

Milton did not very long continue inactive in the public caufe, and his principles made it no matter of doubt which fide he fhould efpoufe in the contentions of his country. Confcious of his own proper ftrength, and fenfible that genius armed with knowledge was a power of far greater and more extenfive efficiency than the bodily force of any individual, he accordingly decided in favour of the pen againft the fword; and ftationed himfelf in the clofet, where he was himfelf a hoft, rather than in the field, where every mufcular private man would have been his fuperior. In the year 1641 he publifhed four treatifes relative to church government, in which he attacked epifcopacy, and fupported the caufe of the Puritans. Thefe were followed by another in the next year, relative to the fame controverfy, and he reckoned among his antagonifts fuch men as bifhop Hall and archbifhop Ufher. His father, who had been molefted in his refidence by the king's troops, came to live with him, and fpent his latter years, in tranquillity, under his fon's roof. In 1643, Milton married Mary, daughter of Richard Powell, efq., a magiftrate in Oxfordfhire. This was a very unfuitable connection, for the father-in-law was a zealous royalift, and the daughter had been accuftomed to the jovial hofpitality of the country gentlemen of that party. After a month's experience of her new life, the lady fighed for the gaieties which fhe had left, and obtaining permiffion, by the earneft requeft of her relations, for a fhort abfence, fhe revifited her native place. Here fhe continued during the remainder of the fummer, nor could the letters, meffages, and remonftrances of her hufband bring her back. Incenfed at her neglect and ill treatment of him, he began to confider her conduct as a defertion of the nuptial contract, and refolved to punifh it by repudiation. He foon found arguments to juftify it to the world, and publifhed, in 1644, "The Doctrine and Difcipline of Divorce," which was followed by "The Judgment of Martin Bucer concerning Divorce." By thefe writings the fury of the Prefbyterian clergy was inftantly kindled, and they procured the author to be fummoned before the houfe of lords, but that body did not choofe to enter into the queftion, and foon difmiffed him. The Prefbyterians were now left without any confolation for the lofs of an able friend, and the excitement of a formidable enemy. Milton now was irrevocably alienated from their caufe, and he foon fully difcovered that many of thefe pretended zealots of liberty fought only their own aggrandizement, and the power of impofing upon others a yoke which they had themfelves been unable to bear. On the fubject of divorce he makes out a ftrong cafe, and appealed to the whole tenour of the fcripture; the laws of the firft Chriftian emperors; the opinions of the moft eminent among the early reformers; and endeavours to fhew that by the laws of God, and by the inferences of the moft virtuous and enlightened men, the power of divorce ought not to be rigidly reftricted to thofe caufes which render the nuptial ftate unfruitful, or which taint it with fpurious offspring. Regarding mutual fupport and comfort as the principal objects of this union, he contends, that whatever defrauds it of thefe ends effentially vitiates the contract, and muft neceffarily juftify its diffolution.

Milton, in conformity to this theory, refolved practically to act upon it, and began to pay his addreffes to a young lady of great accomplifhments, the daughter of a Dr. Davies. The rumour of the intended alliance effected what his remonftrances had been unable to do; as he was paying a vifit to a neighbour, he was furprifed with the fudden appearance of his wife from another room, who threw herfelf at his feet and implored forgivenefs. After a fhort ftruggle of refentment, he relented, and took her again to his bofom. The reconciliation was lafting and fincere, and Milton nobly fealed it by opening his houfe to her father and brothers, when they had been driven from home by the triumph of the republican arms. He was now obliged to take a larger manfion, and removed to Barbican. In this afylum his wife's relations continued, till the queftion refpecting their property was adjufted with the government, and till a period fubfequent to the death of Milton's father. Under the preffure of thefe domeftic embarraffments, and of the public intereft, the intellect of our author, obedient to a heart actuated by the pureft benevolence, was bufy in promoting the welfare of the human race. In the year 1644, he imparted to the world his ideas on the fubject of education, and defended, with a power which has never been exceeded, that guardian of liberty and truth, the freedom of the prefs.

His "Tractate on Education," addreffed to Mr. Hartlib, the friend of fir William Petty, contains his thoughts on that important fubject. From this it appears, he conceived it poffible to initiate the young ftudent into fcience and language by the fame procefs, and to make an acquaintance with things the immediate refult of an acquaintance with words. Between the years of twelve and twenty-one, the pupil is to be led through various languages from grammar to ethics, logic, rhetoric, politics, law, theology, criticifm, and the practice of compofition. Geography was to exhibit to him the furface of the globe, and the principles of aftronomy were to unfold to him the heavens; natural philofophy, comprehending anatomy and phyfiology, was to make him converfant with the phenomena of nature, and with the wonders of his own frame; the mathematics were to introduce him to the fciences of architecture, engineering or gunnery, fortification, and navigation. With this kind of education, Milton's pupil was to be accomplifhed, and fit for any duty to which his country might fummon him, in the pulpit or at the bar, in the fenate or the field. During the courfe of thefe ftudies, the body of the ftudent was to receive its due fhare of cultivation, to be maintained in health by temperance, and to be invigorated by exertion. This little piece is written in an eafier and purer ftyle than the preceding works of its author; but in every fpecies of merit it muft yield to another compofition, produced nearly at the fame time, by the fame pen, and addreffed to the parliament, with the title of "Areopagitica, or a fpeech for the liberty of unlicenfed printing." The Prefbyterians, on their rifing into power, forgot the principles which they had profeffed in their adverfity; and, declaring againft unlimited toleration, difcovered by their readinefs to violate the rights of others, that their tendernefs was only for their own. Againft thefe apoftates to the caufe of liberty, Milton advanced as the champion of free difcuffion; and the effect of his zeal in this inftance, for the interefts of genuine liberty, has received the unanimous acclamation of the world. Though his controverfial, and other engagements, had for fome time fufpended the exertion of his poetical talents, yet he did not fuffer his character as a poet to fink into oblivion, and in 1645, he publifhed his juvenile poems in Latin and Englifh. In 1646, Milton's wife produced her firft child, and in the following year, in which his father died, the Powells returned to their own manfion, and his houfe was refigned once more to literature. In this houfe, in which his fecond daughter Mary was born, he did not continue long, but exchanged it for one of fmaller dimenfions in High Holborn. His next removal was occafioned by his acceptance of the office of Latin fecretary, which rendered a fituation nearer to Whitehall an object of convenience

Milton's principles of the origin and end of government, carried him to a full approbation of the trial and execution of the king, which was the final cataftrophe of the civil wars; and in order to conciliate the minds of the people, which were agitated by the outcries, as well of the Prefbyterians as the loyalifts againft that act, he publifhed early in 1649, a work, entitled "The Tenure of Kings and Magiftrates," proving that it is lawful, and that it hath been fo held through all ages, for any who have the power, to call to account a tyrant or wicked king, and, after due conviction, to depofe and put him to death, if the ordinary magiftrate have neglected or denied to do it. He foon after attempted to fupport the new order of things, by a pamphlet animadverting upon the revolt of the Scotch Prefbyterians, fettled at Belfaft, from the parliament. With the view of preferving the republican fpirit of the nation, he alfo employed himfelf in compofing "A Hiftory of England" from the earlieft periods, of which he wrote fix books, but left the work unfinifhed. His progrefs was ftopped by an appointment to the Latin fecretaryfhip to the council of ftate. Scarcely was Milton feated in his new office, when he was fummoned by the government to the difcharge of a duty, well adapted to the extent of his powers, and one of confiderable importance; it was to write an anfwer to the famous royal work, as it was then fuppofed to be, entitled "Icon Bafilikè," or the portraiture of his facred majefty in his folitudes and fufferings. Milton chofe for the title of his work "Iconoclaftes," or Image-breaker: this piece, fays his biographer, Dr. Symmons, "may be regarded as one of the moft perfect and powerful of Milton's controverfial compofitions. Preffing clofely on its antagonift, and tracing him ftep by ftep, it either expofes the fallacy of his reafoning, or the falfehood of his affertions, or the hollownefs of his profeffions, or the convenient fpeciousnefs of his devotion. In argument, and in ftyle compreffed and energetic, perfpicuous and neat, it difcovers a quicknefs which never miffes an advantage, and a keennefs of remark which carries an irrefiftible edge." This work was firft printed in 1649, and a fecond edition of it appeared in the following year; it was publifhed again in London in 1652, in a French tranflation, and was anfwered in 1651, in a work, entitled "Icon-aclaftes," or the Image unbroken, and alfo forty years afterwards in another piece, called "Vindiciæ Carolinæ." We have in the article GAUDEN fhewn that the "Icon-Bafilikè" was written by that prelate, and not by king Charles, to whom it was generally imputed. This has been fatisfactorily proved by the affertions of the two fons of the king, *viz* Charles II. and James II.; by letters of the lord chancellor Hyde, and Dr. Gauden himfelf; and by the fpecific depofitions of the doctor's friend Dr. Walker, and of his widow. Doubts of the real author of the "Icon Bafilikè" were entertained almoft immediately upon its publication by Milton, and by other perfons. Milton probably had no doubt whatever of its fpurioufnefs, but was without any fpecific evidence to bring home the charge, he therefore anfwered the book, and its arguments, without regard to the writer, for he exprefsly fays, "But the matter, here confiderable, is not whether the king, or his *houfhold rhetorician*, have made a pithy declamation againft tumults, but firft, whether there were tumults or not, &c." It was alfo, in the year 1649, attacked as the work of a clergyman who was looking to preferment as a reward, in an able piece, entitled "Icon-alethinè," or the true image. To this work is prefixed a frontifpiece, in which, on a curtain being drawn afide, is difcovered a dignitary of the church of England in his full canonical drefs, and beneath are infcribed the following lines:

"The curtain's drawn; all may perceive the plot,
And him, who truly the black babe begot.
Whofe fable mantle makes me bold to fay,
A Phæton Sol's chariot ruled that day.
Prefumptuous prieft! to fkip into the throne;
And make the king, his baftard iffue own!
The author therefore hath conceived it meet,
The doctor fhould do penance in this fheet."

On the appointment of Milton to the office of Latin fecretary, he removed to a lodging at Charing Crofs, and afterwards to apartments in Scotland Yard. Here his wife prefented him with a third child, a fon, who died in his infancy. In 1652 he changed his refidence to Petty France, which he occupied for eight years, till the crifis of the reftoration, a handfome houfe opening into St. James's park.

Scarcely had Milton finifhed his reply to the "Icon Bafilikè," than he was called upon to juftify the principles of the commonwealth in England, in oppofition to Salmafius, an honorary profeffor in the univerfity of Leyden, who had been hired by Charles II. to write a work in favour of the royal caufe, which he entitled "Defenfio Regia." Salmafius was, by much, a more powerful antagonift than Dr. Gauden, and the conteft was to be decided in a more ample field, than that in which Milton had engaged with the "Icon Bafilikè." The powers of his mind were now to be exhibited to Europe, and the whole circle of the civilized and Chriftian community was to witnefs his triumph or defeat. In 1651, he performed the tafk allotted him in a work under the title of "Defenfio pro Populo Anglicano;" in this he exercifed all the powers of Latin rhetoric, as well to juftify the republican party, as to confound and vilify the celebrated fcholar againft whom he took up his pen. By this, notwithftanding the party virulence, with which, by the cuftom of the times, it was debafed, he acquired a high reputation both at home and abroad. He was vifited on the occafion by all the foreign ambaffadors then in London, was complimented by feveral eminent fcholars on the continent, and received, as a remuneration for his labours, a thoufand pounds from the Englifh government. His book was generally read by literary enquirers of all parties, while, on the other hand, the work of Salmafius was condemned and fuppreffed by the ftates of Holland. One fource of triumph arofe to Milton's enemies; in confequence of this controverfy, his intenfe application to ftudy deprived him of that fight, which had been for fome years declining. His phyficians had warned him, that the exertion neceffary to accomplifh fuch a work would probably induce total blindnefs, but his attachment to the public caufe of his country and the world, made him readily fubmit to any privations which were merely perfonal, fo that he might render that fervice which the exigencies of the times required.

That fuch were his motives, we have his own declarations, in a fine fonnet addreffed to his friend Cyriac Skinner, which our readers will thank us for tranfcribing.

"Cyriac, this three years day, thefe eyes, though clear
To outward view, of blemifh or of fpot,
Bereft of light, their feeing have forgot;
Nor to their idle orbs doth fight appear
Of fun, or moon, or ftar throughout the year,
Or man or woman;—yet I argue not
Againft Heaven's hand or will, nor bate a jot
Of heart or hope; but ftill bear up and fteer

Right

Right onward What supports me, doſt thou aſk?
  The conſcience, friend, to have loſt them overplied
In liberty's defence, my noble taſk,
  Of which all Europe rings from ſide to ſide:
This thought might lead me through the world's vain maſk,
  Content, though blind, had I no better guide."

And in plain proſe he ſays, in his "Second Defence," "When the taſk of replying to the defence of the king was committed to me, at a time when I had to contend with ill-health, and when one of my eyes being nearly loſt, my phyſicians clearly predicted, that if I undertook the laborious work, I ſhould ſoon be deprived of both; undeterred by the warning, I ſeemed to hear a voice, not of a phyſician, but of ſome internal and more divine monitor; and conceiving that by ſome fatal decree, the alternative of two lots was propoſed to me, that I muſt either loſe my ſight, or muſt deſert a high duty, the two deſtinies occurred to me, which the ſon of Thetis reports to have been ſubmitted to him by his mother, from the oracle of Delphi. Reflecting, therefore, with myſelf, that many had purchaſed leſs good with greater evil, and had even paid life as the price of glory, while to me the greater good was offered at the expence of the leſs evil, as merely by incurring blindneſs, I might ſatisfy the moſt honourable demand of duty; which, intrinſically of more worth even than glory itſelf, ought to be the firſt and deareſt object of every man's regard; I determined to dedicate the ſhort enjoyment of my eye-ſight, with as much effect as I could to the public advantage."

Among the attentions paid to Milton at this time, he was particularly pleaſed with thoſe of Leonard Philarus, a learned Athenian, who had attained to high rank in Italy, and was now employed by the duke of Parma on an embaſſy to the court of Paris. Struck with the ability and ſpirit of Milton's compoſition, this illuſtrious Greek ſent him his portrait, with a letter of panegyric to the defender of the Engliſh commonwealth. On a viſit which Philarus ſoon afterwards made to England, he waited upon Milton, then reduced to a ſtate of total blindneſs, and mutual friendſhip was the conſequence of their perſonal intimacy. When Philarus returned to Paris, he was led, by the celebrity of Thevenot, the phyſician, particularly renowned at that time for his acquaintance with the diſeaſes of the eye, to communicate a hope to Milton of the recovery of his ſight. The letters in which our author acknowledges the kindneſs of his friend on this and other occaſions are preſerved in Dr. Symmons' life of him.

His intellectual powers, however, ſuffered no diminution from this abridgment of the ſenſitive faculties, and he purſued, without intermiſſion, both his official and controverſial employments. In 1652 a book was publiſhed at the Hague, entitled "Regii ſanguinis clamor ad cœlum adverſus parricidas Anglicanos;" the author was Peter Moulin the younger. Milton replied to it in his "Second Defence," to which we have already referred, and which was entitled "Defenſio ſecunda pro Populo Anglicano." In this was a high panegyric upon Cromwell, who had now aſſumed the ſupreme power with the title of Protector. "Milton's ſubſervience and attachment to this uſurper," ſays one of his biographers, "is the part of his conduct which it is the moſt difficult to juſtify. When the wiſeſt and moſt conſcientious of the republicans had become ſenſible of his arts, and had openly oppoſed his ambitious projects, it might have been expected that the mind of Milton would neither have been blinded by his hypocriſy, nor overawed by his power. If the general tenour of his character will exonerate him from the ſuſpicion of intereſted motives on this occaſion, it muſt be ſuppoſed that he was dazzled with the greatneſs of Cromwell's actions, and was convinced that his ſuperiority alone could allay that contention of parties which threatened ruin to the cauſe that had proved victorious in the field. Milton, beſides, was a zealous friend to religious liberty, for which he ſaw no refuge from the intolerance of the Preſbyterians, except in the moderation of the protector. It may be added, that the very paſſage in which he addreſſes Cromwell with the loftieſt encomium, contains a free and noble exhortation, that he ſhould reſpect that public liberty, of which he conſiders him as the guardian."

Milton's office as Latin ſecretary, chiefly regarded tranſactions with foreign nations, in which it is admitted that Cromwell was meritoriouſly attentive to the honour and intereſt of his own. In 1652 he loſt his wife, and his blindneſs, in a ſhort time, induced him to marry again. His ſecond wife was Catharine, the daughter of captain Woodcock of Hackney, who, unfortunately for him, died within a year in child-bed, greatly regretted by her huſband, who has conſecrated her memory by a beautiful ſonnet, ſuppoſed to be the reſult of a dream, immediately after her deceaſe, in which are the following lines:

Methought I ſaw my late eſpouſed ſaint,
* * * * * *
* * * * * *
Came, veſted all in white, pure as her mind:
  Her face was veiled, yet to my fancied ſight
Love, ſweetneſs, goodneſs in her perſon ſhined
  So clear, as in no face with more delight.
But Oh! as to embrace me ſhe inclined,
  I waked;—ſhe fled, and day brought back my night.

Employment was his reſource againſt the gloom of his condition; and after he had concluded his controverſial warfare, he took up his ſuſpended "Hiſtory of England," which he carried on to the conqueſt: he alſo collected materials for a Latin Theſaurus, intended as an improvement upon that of R. Stephanus.

In the buſineſs of his office he had coadjutors; but the moſt important matters were ſtill committed to him, and from his pen proceeded a Latin memorial of great ſtrength and elegance, ſtating the reaſons for the war which the protector declared againſt Spain. A remonſtrance which he drew up concerning the perſecution of the Proteſtants in Savoy, ſtrongly expreſſed his deteſtation of religious tyranny.

After the death of Cromwell, when the fluctuations of government threatened general anarchy, he was induced to give his advice on civil and eccleſiaſtical topics in ſome ſmall publications, one of which was entitled "A Ready and Eaſy Way to eſtabliſh a Free Commonwealth, and the Excellence thereof, compared with the Inconveniences and Dangers of re-admitting Kingſhip." This, as its title imports, was intended rather to expoſe the evils neceſſarily conſequent to the nation's relapſe into its old vaſſalage under kings, and to demonſtrate the preference of a republican to a monarchical government, than to propoſe any juſt model of a popular conſtitution. In this work, as well as in another, entitled "Brief Delineations, &c." he ſhews that he was fearful of an unqualified appeal to the people, and deems them incapable of determining with wiſdom for their own intereſts. It was, however, in vain to contend by pamphlets againſt the national inclination. The king returned in triumph, and Milton was diſcharged from his office, and for a time lay concealed in the houſe of a friend in St. Bartholomew's Cloſe, near Smithfield. Here his privacy from the world was perfect, till after the paſſing of the act of oblivion, in the exceptions of which he was not comprehended, aſcertained

tained his ſafety, and re-inſtated him in ſociety. To whom he was indebted, in this emergency, for his preſervation, is not known with certainty; but it ſeems probable that his life was ſaved principally by the earneſt and grateful interpoſition of ſir William D'Avenant, who had himſelf been formerly preſerved by the mediation of Milton, when ordered by parliament, in 1651, to trial, before the high court of juſtice. (See DAVENANT, WILLIAM.) Milton's name firſt occurs in the proceedings of the new government, in an addreſs from the houſe of commons to his majeſty, that he would iſſue his proclamation to call in Milton's "Defences of the People," and "Iconoclaſtes," together with a book of Goodwyn's, and cauſe them to be burnt by the common hangman, and alſo that the authors ſhould be proſecuted by the attorney-general. The books were accordingly burnt, but the authors were returned as having abſconded.

Now, reduced in his circumſtances, and under the diſcountenance of power, Milton removed to a private habitation, near his former reſidence in the city. But ſcarcely had he left his concealment when he was taken into cuſtody, by an order of the houſe of commons, from which he was diſmiſſed by paying his fees. In 1662, he was reſiding in Jewinſtreet, and from this he removed to a ſmall houſe in the Artillery-Walk, adjoining Bunhill Fields, where he continued during the remaining part of his life.

While living in Jewin-ſtreet, he married his third wife, Elizabeth Minſhull, the daughter of a gentleman of Cheſhire. He was now to reſume that poetical character which, for many years, had been ſunk in that of the controverſialiſt and politician. Undiſturbed by contentions and temporary topics, his powerful mind was left in repoſe, to meditate upon the great ideas which had indiſtinctly riſen to its view, and the reſult of its energies was the "Paradiſe Loſt." Much diſcuſſion has taken place concerning the original conception of this grand performance, but hitherto it has not been traced. It is certain that at the time when he firſt formed the reſolution of writing an epic poem, which was at an early period, he thought of ſome ſubject in the heroic times of Engliſh hiſtory; but the religious turn of his mind, and his aſſiduous ſtudy of the Hebrew ſcriptures, produced a final preference of a ſtory derived from the Old Teſtament. He compoſed in blank verſe, on account of the facility with which he could pour forth the ſtrains that ruſhed into his mind with the force and rapidity of inſpiration. His nephew Philips had the peruſal of it, from the very beginning, in parcels of ten, twenty, or thirty verſes at a time, which, being written by any perſon that was near at hand, probably wanted correction as to the orthography and pointing. This gentleman ſays, upon the authority of Milton, that his vein never happily flowed but from the autumnal equinox to the vernal, and that whatever he attempted at other times was never to his ſatisfaction. The exact time occupied in the compoſition of the Paradiſe Loſt is not known; it was finiſhed in 1665, when Milton, to avoid the contagion of the plague, through the kindneſs of his friend Elwood, a quaker, made a retreat to Chalfont, in Buckinghamſhire. It was firſt printed in 1667, in ten books, and he received from the bookſeller five pounds for the copyright, with a contingency of ten more, depending on the ſale of two other editions, and which he lived to receive. Theſe fifteen pounds, however, purchaſed only the bookſeller's right to the ſeveral editions for which they were paid, as Milton's widow ſold the irrevertible copyright of the work which had been bequeated to her, for eight pounds, to the ſame bookſeller, Samuel Simmons, who, almoſt immediately, diſpoſed of what was thus wholly transferred to him, for twenty-five pounds to Aylmer, another bookſeller, from whom it paſſed, at a conſiderable advance, to Jacob Tonſon. Much has been ſaid of the deplorably low price advanced for this immortal work, "but," ſays Dr. Symmons, "if we would regard ourſelves placed in the middle of the ſeventeenth century, and immerſed in all the party violence of that miſerable period, we ſhould rather be inclined to wonder at the venturous liberality of the bookſeller, who would give even this ſmall conſideration for the poem of a man living under the heavieſt frown of the times, in whom the *poet* had long been forgotton in the polemic, and who now tendered an experiment in verſe, of which it was impoſſible that the purchaſer ſhould be able to appreciate the value, or ſhould not be ſuſpicious of the danger. It is certain that the world was, at that period, incapable of doing it juſtice, and it was long before it took a ſecure place among thoſe productions which continually riſe in eſtimation, and are unlimited by time or place. Milton, conſcious of its merits, anticipated his final ſucceſs, and was, in that expectation, ſupported amidſt temporary diſcouragements." The thirteenth edition was printed, with a life by the author, in 1727, by Eliſha Fenton, who was a ſcholar, a poet, and a man of worth, though not without his failings. See FENTON.

In 1671 Milton publiſhed his "Paradiſe Regained," written upon the ſuggeſtion of his friend Elwood, who, on having read the Paradiſe Loſt in manuſcript, and being aſked by the author how he liked it, anſwered, in his quaint way, "Thou haſt ſaid much here on Paradiſe Loſt; but what haſt thou to ſay of Paradiſe Found?" When the latter poem was finiſhed, he put it into the hands of Elwood, ſaying, in a pleaſant tone, "this is owing to you, for you put it into my head by the queſtion you put to me at Chalfont." This was probably regarded by the author as the theological completion of the plan commenced in Paradiſe Loſt, and he viewed it with the partial fondneſs of an aged parent for his lateſt offspring. But in point of grandeur and invention its inferiority is extremely apparent, yet modern criticiſm has pronounced it by no means unworthy of the genius of Milton, allowance being made for the narrow compaſs of the ſubject, and his particular purpoſe in writing it.

At the ſame time that this was publiſhed, appeared his tragedy of "Sampſon Agoniſtes," compoſed upon the ancient model, and never intended for the ſtage. It cannot be ſaid to entitle the author to a place among thoſe dramatic writers who have diſtinguiſhed themſelves by the talent of moving the paſſions, or of delineating the character; but its moral and deſcriptive beauties are not inconſiderable. The impreſſion made on the author's mind by the ſufferings of his party, and by his own depreſſed ſtate, may be diſtinctly traced in ſome of its pathetic and animated ſtrains, ſuch as in thoſe that follow:

"God of our fathers! what is man!
That thou towards him with hand ſo various
Or, might I ſay, contrarious,
Temper'ſt thy providence through his ſhort courſe
Not evenly, as thou ruleſt
The angelic orders, and inferior creatures mute,
Irrational and brute.
Nor do I name of men the common rout,
That wand'ring looſe about
Grow up and periſh, as a ſummer fly.
Heads without name, no more remembered;
But ſuch as thou haſt ſolemnly elected,
With gifts and graces eminently adorned,
To ſome great work, thy glory,
And people's ſafety, which in part they effect:

Yet towards these, thus dignified, thou oft
Amidst their height of noon,
Chang'st thy countenance and thy hand, with no regard
Of highest favours past
From thee on them, or them to thee of service.
Not only dost thou degrade them, or remit
To life obscured, which were a fair dismission,
But throw'st them lower than thou didst exalt them high."

With the Sampson Agonistes Milton's poetical account closes; but writing was become so much a habit with him, that he was continually making additions to his works in prose. In 1672 he published "A System of Logic, after the Manner of Ramus;" and in the following year he ventured again in the field of polemics, with "A Treatise of true Religion, &c. and the best Means to prevent the Growth of Popery." The latter was become the dread of the nation, and Milton was among the most zealous of its opponents. The principle of toleration which he lays down is agreement in the sufficiency of the scriptures; and he denies it to the Papists, because they appeal to another authority. So imperfect was Milton's notion of religious liberty: it is, however, to his credit, that even in this he was contending with popery, avowedly patronized by the duke of York, and secretly countenanced by the king. "The danger," says his biographer, "which at this instant awakened the fears of Milton, became not long afterward so palpable and striking as to excite the nation, united in one great effort for its safety, to depose the Catholic bigot who occupied and abused the throne."

In the same year Milton published a second edition of his youthful poems, with his "Tractate on Education," in one volume, in which he included some pieces not comprehended in the edition of 1645. In 1674 he gave the world his familiar letters and some college exercises, the former with the title of "Epistolarum Familiarum Liber unus," and the latter with that of "Prolusiones quædam oratoriæ in Collegio Christi habitæ." The next exercise of his pen, was, it is said, to translate into English the declaration of the Poles, on their elevating John Sobieski to their elective throne, but Dr. Symmons is doubtful of the fact; thinking it much more certain that in some part of the same year he wrote "A brief History of Muscovy," which was published at a period of about eight years after his death. With this work terminated his literary labours; for the gout, which had for many years afflicted him, was now appointed to terminate his valuable life. He sunk tranquilly under an exhaustion of the vital powers on the eighth of November, 1674, when he had nearly completed his sixty-sixth year. His remains were carried from his house in Bunhill Fields to the church of St. Giles, Cripplegate, with a numerous and splendid attendance, and deposited in the chancel near those of his father. No monument marked the tomb of this great man, but one was erected to his memory in Westminster Abbey, in 1737, at the expence of Mr. Benson, one of the auditors of the imprest. His bust has since been placed in the church where he was interred, by the late Samuel Whitbread, esq.

In the July preceding his death, Milton had requested the attendance of his brother Christopher, and in his presence made a disposition of his property by a formal declaration of his will. This mode of testament, which is called *nuncupative*, was set aside, on a suit instituted by his daughters. By this nuncupative will he had given all his property to his widow, assigning nothing to his daughters, but their mother's portion, which had not yet been paid. On this account, and from exacting from his children some irksome services, such as reading to him in languages which they did not understand, which were necessities resulting from his blindness and his indigence, he has been branded as an unkind father. But the nuncupative will, discovered some years since, shews him to have been amiable, and injured in that private scene, in which alone he has generally been considered as liable to censure, or rather, perhaps, as not entitled to affection. In this will, published by Mr. Warton, and in the papers connected with it, we find the venerable parent complaining of "unkind children," as he calls them, for leaving and neglecting him because he was blind, and we see him compelled, by their injurious conduct, to appeal against them even to his servants. By the deposition of one of those servants, it is certain, that his complaints were not extorted by slight wrongs, or uttered by capricious passion on trivial provocations: that his children, with the exception of the youngest, would occasionally sell his books to the dunghill women, as the witness calls them. That these daughters were capable of combining with the maid-servant, and of advising her to cheat her master, and their father, in her marketings; and that one of them, Mary, on being told that her father was married, replied, "that was no news; but if she could hear of his death that would be something."

We cannot better conclude our account of Milton than in the words of his liberal and eloquent biographer, Dr. Symmons, to whose work we have already acknowledged our obligations, and to which we earnestly refer the readers of the New Cyclopedia, in order that they may see how much more is recorded of our illustrious countryman, than can possibly be compressed in this article. Milton, says Dr. Symmons, was "a man in whom were illustriously combined all the qualities that could adorn, or elevate the nature to which he belonged; a man, who at once possessed beauty of countenance, symmetry of form, elegance of manners, benevolence of temper, magnanimity and loftiness of soul, the brightest illumination of intellect, knowledge the most various and extended, virtue that never loitered in her career nor deviated from her course;—a man who, if he had been delegated as a representative of his species to one of the superior worlds, would have suggested a grand idea of the human race, as of beings affluent with moral and intellectual treasure, who were raised and distinguished in the universe as the favourites and heirs of heaven."

Of the three daughters of Milton, Anne, the eldest, married a master-builder, and died with her first child in her lying-in. Mary, the second, died in a single state: and Deborah, the youngest, married Abraham Clarke, a weaver in Spitalfields. She had seven sons and three daughters, but of these she left, at her decease, only Caleb, who marrying in the East Indies, had two sons whose history cannot be traced; and Elizabeth, who married Thomas Foster, of the same business with her father, and had by him three sons and four daughters, who all died young and without issue. Mrs. Foster died in poverty and distress, on the ninth of May, 1754, "and with her, it is highly probable, expired the last descendant of the immortal Milton." Symmons's Life of Milton. Biog. Brit. Gen. Biog. Bayle's Dict. Newton's Life of Milton, and Milton's Works.

MILTON, in *Geography*, a parish in the lower half hundred of Toltingtrough, lathe of Aylesford, and county of Kent, England, is situated 22 miles from London, and forms the east side of the town of Gravesend, with which it was incorporated in the reign of queen Elizabeth. Milton was returned, under the population act of 1801, as containing 322 houses, occupied by 2056 inhabitants. The church, which stands near the sea-shore, about a mile from Gravesend,

end, is built of flints and rag-stones: round it formerly stood the village of Milton, of which only one house is now left. See GRAVESEND.

MILTON, or *Middleton*, as anciently called, a market town and parish in the upper half hundred of Milton, in the lathe of Scray, and county of Kent, England, is of very remote antiquity, and formed part of the demesnes of the Saxon kings. It is situated 12 miles from Maidstone, and 39 from London, on the acclivity of a hill, about half a mile from the high road, sloping down to a small creek which falls into the river Swale, about two miles to the north-west. The vicinity of this town to the Swale, which separates the isle of Sheppey from the main land, was the cause of its being frequently plundered by the Danes during their piratical incursions in the ninth century. Here their veteran chief, Hastings, endeavoured to establish himself in the time of Alfred; and the remains of his encampment or fortress are still to be seen in the marshes of Kemsley Downs, between Milton church and the mouth of the creek. It consists of a high rampart and broad ditch, inclosing a square area, the sides of which are nearly parallel with the cardinal points of the compass. It measures about an hundred feet each way, and has obtained the name of Castle-Rough, from its having been long overgrown with trees and underwood.

Milton is supposed to have originally stood in the vicinity of its church, which is considerably to the north of the present town; and near it the Saxon kings had a palace, which was burnt, together with the town, by earl Godwyn, during his quarrel with Edward the Confessor, about the year 1052. Notwithstanding this, Milton appears to have been a place of considerable importance for the time, in the days of William the Conqueror, who, in the Domesday survey, is recorded to have then held the manor. It remained vested in the crown till the time of Charles I., though frequently granted for life, or a term of years, to different persons; particularly to several queens in dower, and others of the royal blood, who procured various privileges for the inhabitants. The grant of the market, which is kept on Saturdays, was obtained by queen Isabella, in the 13th of Edward II., together with the liberty of holding an annual fair for four days. The town is governed by a portreeve, who is chosen on St. James's day, by such inhabitants of the parish as pay the church and poor's rates. The market-house and shambles stand near the middle of the town; and at a small distance northward is the court-house, an old timber building, where manor courts and other public meetings are held; beneath it is the town gaol. The church is a spacious fabric, and consists of two aisles and two chancels, with a massive embattled tower at the west end, which, together with the south chancel, is composed of squared flints, laid in even rows. The east windows are large, and pointed: that of the north chancel is divided into five lights, with numerous crockets above; the other has four trefoil-headed lights below, with three ranges of quatrefoil lights above. The south chancel, which belonged to the ancient family of Northwood, contains a piscina, and several tombs and sepulchral memorials.

The number of houses in this parish, as returned in the year 1801, under the population act, was 322; that of inhabitants 2056. The Oyster Fishery furnishes the principal source of employment to the latter, and has done so for many centuries. In the reign of king John, the right of this fishery in the manor and hundred of Milton was granted to the abbey at Faversham, to which it appertained at the dissolution. It then was held by the crown till the reign of Charles I.: since that period it has been granted, with the manor, to various persons successively; and is now held on lease by a company called Free Dredgers, who are governed by their own particular rules or bye-laws, made, according to ancient custom, at the court-baron of the manor. The oysters produced within the limits of this fishery are in high estimation, under the name of "Native Miltons." There are four wharfs belonging to this town; and considerable quantities of corn, and other produce of the adjacent country are shipped here for the London markets, commodities of every kind being freighted in return.

In the western part of this parish and its vicinity is a large tract of woodland, called Chesnut Woods, from the great plenty of those trees which grow therein: and in a presentment made of the customs of Milton, in 1575, it is mentioned, that the occupiers of three mills holden of the manor, should gather yearly for the lord of it nine bushels of "chestenottes" in Chesnot Wood, or pay eighteen-pence by the year to the queen.

In the marshes in the north-west quarter of the parish is a decoy for wild fowl, of which great numbers are taken, and principally sold in the markets of the metropolis. Hasted's History of Kent, vol. vi. Beauties of England and Wales, vol. viii. by E. W. Brayley.

MILTON, a township of America, in Chittenden county, New York, on the E. side of lake Champlain, opposite to South Hero island; divided into nearly equal parts by La Moille river, which discharges itself into the lake in Colchester. The township contains 786 inhabitants.—Also, the "Uncataquisset" or "Unquaty" of the ancient Indians, a post-town in Norfolk county, Massachusetts, adjoining to Dorchester; 7 miles S. of Boston: containing 1143 inhabitants, three paper-mills, and a chocolate-mill. It was incorporated in 1662; and affords one of the finest prospects in America.—Also, a town in the county of Saratoga, in New York, containing 2123 inhabitants.—Also, a post-town in Cayuga county, New York, on the N.E. side of Cayuga lake, 40 miles N. of Tioga river; incorporated in 1794, and containing 3553 inhabitants.—Also, a small post-town in Albemarle county, Virginia, on the S.W. side of the Rivanna, about 80 miles N.W. by W. of Richmond.—Also, a post-town of Northumberland county, Pennsylvania; 219 miles from Washington.

MILTOWN-MALBAY, a post-town of Ireland, in the county of Clare. It is built on a bank running down to the sea, facing the south-west. There are here hot and cold baths, and it is much frequented as a bathing-place. It is 128 miles W.S.W. from Dublin. Carlisle. Wakefield.

MILTSCHIN, a town of Bohemia, in the circle of Bechin; 10 miles N. of Tabor.

MILTUS, in *Botany*, so called by Loureiro, from μίλτος, *red lead*, or *vermilion*, the whole plant being as that author says of a beautifully vivid red colour.—Loureir. Cochinch. 303.—Class and order, *Dodecandria Pentagynia*. Nat. Ord. *Caryophyllei*, Linn.? *Ficoideæ*, Juss.?

Gen. Ch. *Cal.* Perianth inferior, of five, ovate, concave, rugose, coloured, spreading, permanent segments. *Cor.* none. Nectary none. *Stam.* Filaments twelve, affixed to the bottom of the calyx, and shorter than it; anthers ovate, twin, erect. *Pist.* Germen superior, roundish, furrowed; style none; stigmas five, linear, bent backwards. *Peric.* Capsules five, approaching each other, ovate, rough, single-seeded. *Seed* ovate, shining.

Eff. Ch. Calyx of five leaves, inferior. Corolla none. Capsules five, single-seeded.

Obs. Loureiro remarks that the difference between this genus and *Glinus* is not very great.

1. M. *africana*. Loureir.—A native of dry places at Mozam-

Mozambique, an African iſland.—All that we know of this plant is from the deſcription of the above quoted author, which is as follows. *Stem* ſhrubby, much divided, about four feet long, ſlender, proſtrate, ſmooth. *Leaves* oblong, entire, obtuſe, thick or fleſhy, ſmooth, the leſſer ones nearly ſeſſile, oppoſite, and crowded. *Flower-ſtalks* ſimple, many together, lateral.—The ſtems, flowers, and leaves are all of a remarkably ſtriking red or vermilion colour.

MILVAGO, in *Ichthyology*, a name given by Geſner and ſome others, to a fiſh called by authors in general *milvus*, and by ſome *lucerna*, and the *flying-fiſh*. It is a ſpecies of the trigla, and is called, by Artedi, the trigla with a ſnout bifid at the extremity, and the ſide-lines forked near the tail.

MILVERTON, in *Geography*, a market-town in the hundred of the ſame name, and county of Somerſet, England. It is ſituated in a woody fertile country, pleaſingly diverſified with hill and valley, at the diſtance of eight miles from Taunton, and five from Wellington. The buildings are chiefly arranged in three irregular ſtreets; and the church ſtands on an eminence in the centre. This town was anciently a borough, the manor whereof is now veſted in the crown, and long poſſeſſed a good trade in ſerges and druggets. The manufacture of theſe articles, however, is now almoſt entirely dropped, but an extenſive manufactory of flannels has been eſtabliſhed of late years. Though entirely deprived of its privileges as a borough, it continues to be governed by a portreeve; and ſearchers and ſealers are ſtill annually appointed. The petty ſeſſions are held here. Friday is the market day, and there are two fairs during the year, one on the 25th of July, and another on the 10th of October. The population of the town and pariſh, according to the returns of 1801, was 1667 perſons.

Milverton is remarkable in hiſtory as having given name to John de Milverton, the Carmelite friar of Briſtol, who was celebrated for his zealous oppoſition to the doctrines of Wickliff, the firſt Engliſh reformer. Collinſon's Hiſtory and Antiquities of Somerſetſhire, vol. iii. 4to.

MILUS, μιλος, a name given by the Greek writers to a plant uſed in garlands, and ſometimes to a tree. Theophraſtus evidently uſes it as the name of a tree, and Crato as that of the garland-herb,

MILVUS, in *Ichthyology*. See FLYING-*Fiſh*, CALLYONIMUS *Lyra*, and DRAGONET.

MILVUS, in *Ornithology*, the name of the kite and buzzard. See FALCO.

MILWALDE, or MIDWALDE, in *Geography*, a town of Holland, in the department of Groningen; 8 miles S.S.E. of Dam.

MIMA, a town of Japan, in the iſland of Xicoco; 23 miles N.W. of Awa.

MIMANSA, in *Philoſophy*, is the name of a theory upheld by a numerous ſect of Hindoos, among whom, however, even of this ſchool, there is conſiderable diverſity of opinion. The word Mimanſa denotes, in Sanſcrit, the operations and concluſions of reaſon. The doctrines are divided into the firſt and ſecond. The firſt, called Purva Mimanſa, or Karma Mimanſa, is ſaid to have been promulgated by Jaimini in twelve chapters; it diſcuſſes queſtions of law, and moral and religious duties. (See JAIMINI.) The ſecond diviſion is called Vedanta, and is attributed to Vyaſa, who is ſometimes ſaid to have been the maſter or preceptor of Jaimini. (See VEDANTA and VYASA; and the articles MURTY and MYSTICAL *Poetry* for ſome of the tenets of the Vedanti ſchool.) Both the Mimanſas profeſs to ſhew what acts are pure or impure, what objects are to be deſired or avoided, and by what means the ſoul may aſcend to the Firſt Principle. Compared with the Grecian ſchools, the Mimanſa approaches neareſt the Platonic, having, indeed, many conſonant ideas and doctrines.

MIME. MIMUS, a term in the ancient comedy, ſignifying a *buffoon*, or *mimic*, who acted by poſtures ſuitable to the perſon or ſubject he repreſented.

The word comes from the Greek μιμος, *imitator;* formed of μιμεομαι, *I imitate*. The ſame comedians were alſo ſometimes called *pantomimes*, becauſe of their counterfeiting all manner of poſtures and geſtures.

According to Lucian (de Saltatione), a ſingle dancer, or mime, was able to expreſs all the incidents and ſentiments of a whole tragedy or epic poem by dumb ſigns, but ſtill to muſic, as in the ancient recitation, and in modern pantomime entertainments; though Ariſtotle expreſsly ſays, that dancers want neither poetry nor muſic; as by the aſſiſtance of meaſure and cadence only, they can imitate human manners, actions, and paſſions. See BATHYLLUS and *Pylades*.

Plutarch (Sympoſ. l. vii. probl. 8.) diſtinguiſhes two kinds of pantomime: one was called υποθεσιν, the ſubject of which was decent and decorous, as well as the manner of expreſſing it, and this nearly approached to comedy. Buffoonery and indecency conſtituted the other.

Sophron of Syracuſe, who flouriſhed in the time of Xerxes, was reputed the inventor of ſerious and decorous pantomime, replete with leſſons of morality. Plato had great pleaſure in the peruſal of the pantomimes of this author. But the Greek drama was ſcarcely formed, ere theatric writers and actors endeavoured more to divert the people by farces and repreſentations of vicious ſcenes and characters, than to improve their morals. Such were the means by which interludes on the ſtage were rendered agreeable to the people of Greece.

The Romans were equally pleaſed with pantomime, and formed of it a fourth ſpecies of drama. The actors diſtinguiſhed themſelves by a licentious imitation of the manners of the times, as appears by the following verſe of Ovid.

"Scribere ſi fas eſt imitantes turpia Mimos."

The mimes uſually acted without ſocks or ſtockings, whereas the three others wore ſocks or buſkins. Their heads were cloſe ſhaved, like the fools on mountebank ſtages; their dreſs, like that of our harlequins, was compoſed of bits of cloth or linen of different colours. This dreſs was called *Panniculus centumculus*. They ſometimes alſo appeared in magnificent ſenatorial robes of purple, to divert the people by the ridicule and contraſt of a ſenator's robe, and a ſhaved head and ſocks. Thus harlequin ſometimes on our ſtage is bedight in the garb of a gentleman. To this dreſs they joined licentious language, and all kinds of ridiculous poſtures, neglecting nothing that could amuſe the populace.

This kind of diverſion was given even at funerals, and the actors were called *Archimimes*. They went before the coffin, and deſcribed by their geſtures the actions and manners of the deceaſed: his virtues and vices, all were exhibited. The propenſity which the mimes had to raillery, inclined them rather to reveal their frailties, than paint their virtues, or any thing that could redound to their honour.

The applauſe given to the pieces of Plautus and Terence, did not prevent even the better ſort from admiring theſe pantomimic farces, when enlivened by wit, and not debaſed by indecency. The Mimographic poets of the Romans, who chiefly diſtinguiſhed themſelves in theſe dramatic exhibitions, were Sneius Mattius, Decimus Liberius, Publius Syrus, under Julius Cæſar; Philiſtion, under Auguſtus; Silo, under Tiberius; Virgilius Romanus, under Trajan;

and Marcus Marcellus, under Antoninus. But the most celebrated of all these were Decimus Liberius, and Publius Syrus. The first diverted Julius Cæsar so much that he made him a Roman knight, and conferred on him the privilege of wearing gold rings. He had such a wonderful talent at seizing ridicule, as to make every one dread his abilities. To this Cicero alludes, in writing to Trebutius, when he was in Britain with Julius Cæsar, telling him, that "if he is absent much longer inactive, he must expect to be attacked by the mime Liberius." Publius Syrus, however, gained so much more applause, that he retired to Puzzoli, where he consoled himself for his disgrace and the inconstancy of the people, and the transient state of human affairs, by the following admirable verse:

"Cecidi ego: vadet qui sequitur; laus est publica."

We with difficulty can imagine some of the grave and judicious reflections of Syrus to be extracted from the pantomimes which he exhibited on the stage: we should rather take them for maxims moulded on the sock or buskin. Encycl. 1st edit.

"Sweet Polhymnia, see advance,
Mother of the graceful dance:
She who taught th' ingenious art
Silent language to impart:
Signs for sentiment she found,
Eloquence without a sound:
Hands loquacious save her lungs,
All her limbs are speaking tongues."

MIMESIS, μιμησις, in *Rhetoric*, a figure, whereby the words, gestures, speech, actions, &c. of another person are imitated. See IMITATION.

MIMETES, in *Botany*, so called by Mr. Salisbury (according to Mr. Brown); apparently from μιμητης, *a mimic*, but we know not its particular application. Brown Tr. of Linn. Soc. v. 10. 105. Ait. Hort. Kew. ed. 2. v. 1. 197. (Hypophyllocarpodendron; Boerh. Lugd-Bat. ed. 2. v. 2. 205. t. 205, 206.)—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Proteæ*, Juss.

Ess. Ch. Corolla regular, in four deep segments. Stamens in the concave tips of the segments. Nectary four scales beneath the germen. Nut superior, sessile, smooth. Common receptacle flat, many-flowered. Scales deciduous.

Eleven species of this genus, all from the Cape of Good Hope, are described by Mr. Brown, four of which, introduced by Mr. Masson between the years 1774 and 1795, are cultivated at Kew. They are all *shrubs*, of a stout tortuous habit; their *leaves* either entire, or furnished with callous teeth. *Flowers* aggregate, generally axillary, sometimes embraced by a sort of hooded leaf, sometimes terminal. *Involucrum* of many imbricated, membranous, rarely coriaceous, leaves, sometimes turned all to one side. *Pistils* longer than the corolla, which becomes flaccid after its expansion. *Stigma* cylindrical, slender, for the most part acute. In *M. capitulata* however, Mr. Brown's second species, it is thickened and conical at the summit. In *M. purpurea*, his last, the *receptacle* is destitute of scales.

The following examples are sufficient.

M. *hirta*. Hairy Mimetes. Br. n. 1. (Protea hirta; Linn. Mant. 188. Lepidocarpodendron foliis sericeis brevibus, confertissimè natis; fructu gracili longo; Boerh. Lugd-Bat. v. 2. 194. t. 194. Leucadendron hirtum; Linn. Sp. Pl. 136.)—Involucrum equilateral, coloured, pointed, eight or ten-flowered. Stigma awl-shaped. Corolla feathery. Leaves acute, entire.—Grows in moist situations. Flowers in the greenhouse from June to August. A bushy *shrub*, with numerous, imbricated, silky *leaves*. *Flowers* reddish.

M. *cucullata*. Three-toothed Mimetes. Br. n. 4. (Protea cucullata; Linn. Mant. 189. Leucadendros africana, sive Scolymocephalos angustiori folio, apicibus tridentatis; Pluk. Almagest. 212. t. 304. f. 6. Hypophyllocarpodendron; Boerh. Lugd-Bat. 206. t. 206. Leucadendron cucullatum; Linn. Sp. Pl. 136.)—Involucrum unequally directed, pointed, nearly smooth. Leaves linear-oblong, three-toothed, smooth: the floral ones dilated below, with recurved margins. Stigma awl-shaped, very acute.—Native of low marshy places, a mile and a half from the Cape. The *leaves* are crowded, tipped with three blunt red teeth. *Flowers* feathery, their long prominent styles reaching far beyond the corolla.

M. *thymelæoides*. Daphne-leaved Mimetes. Br. n. 8. (Leucadendron thymelæoides; Berg. Cap. 19.)—Stem erect. Leaves oval, obtuse, downy, small. Flowers terminal, rather clustered. Style downy below the middle.—*Stem* shrubby, with round, purplish, downy, upright, compound branches. *Leaves* about half an inch long, crowded, spreading, downy, finely fringed; the lower ones becoming smooth. *Flowers* sessile, the size of a small cherry, mostly in pairs. *Leaves* of the *involucrum* elliptical, inclining to lanceolate. *Scales* of the *receptacle* all over densely woolly. *Corolla* silky. *Stigma* rather acute. Of this we find no figure, nor is any thing said of the colour of the flowers.

MIMIZAN, in *Geography*, a town of France, in the department of the Landes, and chief place of a canton, in the district of Mont-de-Marsan. The place contains 413, and the canton 2821 inhabitants, on a territory of 415 kiliometres, in 6 communes.

MIMNERMUS, in *Biography*, a Greek elegiac poet, a native of Colophon, who flourished in the sixth century before Christ, was contemporary with Solon. He was the inventor of the pentameter verse: his compositions were of the elegiac kind, according to the ancient acceptation of the word, which by no means confined it to mournful topics. His talents led him to treat of very different subjects: he was a votary of love and pleasure, and is so distinguished by a line in Propertius:

"Plus in amore valet Mimnermi versus Homero:"

Horace likewise refers to him in a similar connection, though in much stronger terms:

"Si, Mimnermus uti censet, sine amore jocisque
Nil est jocundum, vivas in amore jocisque."

"If, as wise Mimnermus said,
Life unblest with love and joy,
Ranks us with the senseless dead,
Let these gifts each hour employ."

His manners are thought to have corresponded with his philosophy. Of his poems only a few remain, which have been published with the "Novem Feminarum Græcarum Carmina," by Ursinus in 1568, and by Wolfius in 1734.

Mimnermus, according to Plutarch, has rendered himself remarkable, by playing upon the flute a nome called *Cradias*, which, Hesychius tells us, was an air for that instrument usually performed at Athens, during the march, or procession, of the victims of expiation. His elegies, of which only a few fragments are preserved, were so much admired in antiquity, that Horace preferred them to those of Callimachus. (Epist. lib. ii. ep. ii. v. 101.) He composed a poem of this kind, as we learn from Pausanias, upon the battle

battle fought between the people of Smyrna, and the Lydians, under Gyges. He likewife was author of a poem in elegiac verfe, quoted by Strabo (lib. xiv. p. 633, 634. ed. Par.), which he entitled "Nanno," and in which we may fuppofe he chiefly celebrated a young and beautiful girl of that name, who, according to Athenæus, was a player on the flute, with whom he was enamoured in his old age. Horace bears teftimony to his abilities in defcribing that feducing paffion; alluding to fome much admired lines of this Greek poet, which have been preferved by Stobæus:

"Τις δε βιος, τι δε τερπον ατερ χρυσης Ἀφροδιτης, &c.
What is life and all its pride,
If love and pleafure be denied?
Snatch, fnatch me hence, ye Fates, whene'er
The am'rous blifs I ceafe to fhare.
Oh let us crop each fragrant flow'r,
While youth and vigour give us pow'r;
For frozen age will foon deftroy
The force to give or take a joy;
And then a prey to pain and care,
Detefted by the young and fair,
The fun's bleft beams will hateful grow,
And only fhine on fcenes of woe!"

MIMOSA, in *Botany*, fo called from *mimus*, an actor or imitator. *Herba*, or *arbor*, *mimofa*, meaning a fort of imitative plant, whofe motions mimic the fenfibility of animal life. The Senfitive Plant.—Linn. Gen. 548. Schreb. 734. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 438. Juff. 346. Tourn. t. 375. Lamarck Illuftr. t. 846. Gærtn. t. 155. (Acacia; Tourn. t. 375. Inga; Plum. Gen. 13. t. 19.)—Clafs and order, *Polygamia Monoecia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminofæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, very fmall, with five teeth. *Cor.* of one petal, funnel-fhaped, regular, more or lefs deeply five-cleft, fometimes wanting. *Stam.* Filaments capillary, very long, ufually very numerous, fometimes united below; anthers incumbent, fometimes partially abortive. *Pift.* Germen fuperior, oblong; ftyle thread-fhaped, fhorter than the ftamens; ftigma abrupt. *Peric.* Legume long, with numerous tranfverfe partitions. *Seeds* numerous, of various roundifh fhapes.

Obf. Many of the flowers are male, foon falling off; others are female; others furnifhed with both ftamens and piftil, each occafionally more or lefs imperfect; all which circumftances vary in different fpecies.

Mimofa of Tournefort has a jointed legume, and apparently fenfitive, or irritable, leaves.

Acacia of the fame author has a cylindrical legume; the leaves not moving when touched.

Inga of Plumier has a flefhy legume.

No part of the fructification in the genus before us is conftant.

The *calyx*, ufually five-toothed, in fome fpecies is three-cleft.

Corolla ufually of one petal, in fome is of five, in others altogether wanting.

Stamens in fome very numerous, in others ten, five, or four; in fome monadelphous; in fome abortive.

Pericarp a legume, but in fome fpecies flefhy, in others membranous; in fome winged, in others jointed; in fome compofed of four valves.

Seeds of a different fhape in different fpecies.

Eff. Ch. Calyx five-toothed. Corolla regular, five-cleft. Stamens five or more. Piftil one. Legume fuperior, with many cells. Some male flowers.

This vaft genus labours under great uncertainty of character, as appears by the above remarks of Linnæus. For fome of its near allies, fee GLEDITSIA and GYMNOCLADUS. Juffieu has hinted at the propriety of dividing it, according to the number of ftamens, and the ftructure of the legume. This Willdenow has attempted; but to accomplifh it fully, an examination of numerous fpecies in a living ftate would be neceffary; and as moft of them are tropical fhrubs or trees, rarely feen, and ftill more rarely flowering or fruiting, in the gardens of Europe, this defirable end is not at prefent attainable. The foliage is of the pinnate kind, more or lefs compound; in fome irritable, and folding up when touched or fhaken; in all, we believe, drooping and folding together in the dark. A number of paradoxical fpecies as to habit, uniform enough in fructification, have been found in the fouthern hemifphere. Thefe have only a few pinnated leaves when young, bearing fubfequently nothing but fimple, vertical, oblong or linear, dilated and defoliated footftalks, which have all the appearance of leaves, and doubtlefs perform the functions of fuch. A few fpecies bear, in their adult ftate, nothing but angular thorns, ftill lefs like foliage. Yet we know not of any difference in the fructification, between thefe and various uniformly pinnate kinds of *Mimofa*, found likewife in New Holland, which have the habit as well as characters of numerous fpecies heretofore defcribed, natives of Africa, or of the Eaft or Weft Indies.

It is difficult to form a calculation of the fpecies of *Mimofa*. The 14th edition of *Syft. Veg.* contains fifty-three only, fcarcely any of the New Holland ones being there included. Of thefe laft five are figured by Labillardiere, and feveral in Curtis and Andrews; two in Smith's Specimen of the Botany of New Holland. Much more information may be expected from Mr. Brown on this fubject.

The genus is for the prefent fubdivided, by the compofition of its leaves, into feveral fections, of which we fhall offer a few examples.—Some fpecies are furnifhed with thorns, others not.—The roots in general have a ftrong alliaceous fcent.

Section 1. Leaves fimply pinnate.

M. *Inga.* Sweet-bean Mimofa. Linn. Sp. Pl. 1498. (Inga flore albo fimbriato, fructu dulci; Plum. Ic. 14. t. 25. Arbor fylveftris, Belgis *Zoete-boontjes*; Merian. Surin. 51. t. 51.)—Thorns none. Leaves pinnate, of five pair of ovate leaflets, with a jointed bordered ftalk.—Native of South America. A *tree*, with broad, fmooth, ferrated, ribbed *leaflets*. *Flowers* corymbofe, large, green, with many united *ftamens*. *Legumes* often a foot long, tortuous and furrowed; the *feeds* lodged in fweet eatable pulp. The laft circumftance fhews an affinity to *Ceratonia*.

Section 2. Footftalk divided, bearing two or three diftinct pair of leaves.

M. *bigemina.* Pointed Twin-leaved Mimofa. Linn. Sp. Pl. 1499. (Katou-Conna; Rheede Hort. Malab. v. 6. 21. t. 12.)—Thorns none. Leaves pointed, in a double pair. —Native of Malabar. A tall *tree*, with a fœtid though infipid *root*. *Leaflets* ovate, entire, three inches long, fmooth. *Flowers* fmall, white, monadelphous. *Legumes* fpiral, compreffed, their polifhed globofe feeds fufpended by a thread.

Section 3. Leaves conjugate, confifting of two pinnate leaves, on a common footftalk.

M. *fenfitiva.* Broad-leaved Senfitive plant. Linn. Sp. Pl. 1501. (M. fpinofa prima, &c.; Breyn. Cent. t. 16.)—Prickly. Leaves conjugate; each with two pair of half-ovate leaflets; the innermoft lower one very fmall. Petals none.—Native of the Brafils; and of hedges at Lima. This very interefting plant, whofe fenfibility, on account of the large fize of its leaflets, is fo ftriking, was formerly introduced by Houfton into the gardens of England, but is

 no

no longer to be met with. We have seen it at Turin The *footstalks* have a large succulent knot at their base, which appears the chief seat of irritability, and on which the *leaflets* turn, as on a hinge, at the slightest touch. The largest *leaflets* are near an inch and half long; all semi-ovate, bristly beneath. *Flowers* in globular dense heads, on simple axillary stalks. *Legumes* flat, radiating from a centre, bristly and downy.

M. *pudica*. Common Sensitive plant, or Humble plant. Linn. Sp. Pl. 1501. (M. spinosa tertia, &c.; Breyn. Cent. t. 18.)—Prickly. Leaves somewhat fingered, pinnate. Stem hispid. Legumes jointed, fringed.—Native of South America, and of the isle of Bourbon.—This is naturally shrubby, though raised as an annual in our stoves, where it is kept for the sake of its wonderful sensibility. The *leaflets* are very numerous, oblong, obliquely elliptical, rather bristly. If one of them be cut, the shock is communicated, with gradually accelerated rapidity, along the footstalks, to the rest, who all fold softly together, after which the common and partial stalks droop and become pendulous. These have the same tumid pulpy texture at their base as the former. (See LEAVES.) The *flowers* are pale purple, in round, axillary, stalked tufts. *Legumes* near an inch long, composed of three or four orbicular fringed joints.

Section 4. Leaves at least doubly pinnate.

M. *glauca*. Glaucous Mimosa. Linn. Sp. Pl. 1504. (Acacia non spinosa, flore albo, foliorum pinnis latiusculis glabris, siliquis longis planis; Trew. Ehret. 9. t. 36.)—Thorns none. Leaves doubly pinnate, in six principal divisions, and very numerous partial ones. Legumes long, lanceolate, flat.—Native of South America. Cultivated in our stoves, from the time of king William. The delicate glaucous *foliage* is very handsome. *Flowers* white, decandrous, in globular stalked axillary heads, either solitary or in pairs. *Legumes* a span long, acute at each end.

M. *farnesiana*. Sweet-scented Yellow Mimosa. Linn. Sp. Pl. 1506. Acacia indica farnesiana; Ald. Hort. Farnes. 3. t. 2, 4.)—Spines in the place of stipulas, awl-shaped, distinct. Leaves doubly pinnate, in eight principal divisions, and numerous partial ones. Legumes tumid, curved.—Native of Hispaniola. First raised at Rome in 1611. It is scarcely now seen in our stoves. The *leaflets* are small and smooth. *Flowers* deep yellow, in stalked heads, (not sessile as Linnæus says,) valuable for their exquisite fragrance, which excels almost every thing of the kind.

M. *nilotica*. Egyptian Mimosa. Linn. Sp. Pl. 1506. Woodv. Med. Bot. t. 67.—Spines in the place of stipulas, needle-shaped, divaricated. Leaves doubly pinnate, with glands on their common stalk. Heads of flowers on downy stalks, several together.—Native of the Levant. Linnæus mistook this for the true Gum Arabic plant, whose legumes were pasted along with his specimens, and which is another species of *Mimosa*, not well known to us. At least this was the opinion of the late learned Mr. Dryander. Several species, akin to these, produce different sorts of Gum Arabic, or Gum Senegal.

M. *pubescens*. Hairy-stemmed Mimosa. Vent. Hort. Malm. t. 21. Curt. Mag. t. 1263.—Thorns none. Branches hairy. Leaves doubly pinnate, without glands. Leaflets numerous, crowded. Heads of flowers numerous, in long axillary clusters.—Native of New South Wales. A beautiful and fragrant acquisition to the conservatory, remarkable for its rich downy *foliage*, and copious golden *flowers*.

Of the New Holland species with denudated footstalks, assuming the aspect of simple leaves, and which make a fifth most distinct *section*, examples are

M. *myrtifolia*. Curt. Mag. t. 302.

M. *strilla*. Ibid. t. 1121. Andr. Repos. t. 53.

Of those which bear spines only.

M. *verticillata*. Curt. Mag. t. 110.

MIMOSA, in *Gardening*, comprehends plants of the shrubby and under shrubby kinds, of which the species cultivated are, the double-flowered annual sensitive mimosa (M. plena); the lively mimosa (M. viva); the quadrivalve-podded humble mimosa (M. quadrivalris); the sensitive plant (M. sensitiva); the humble plant (M. pudica); the long-twigged mimosa (M. virgata); the spotted-stalked mimosa (M. punctata); the slothful mimosa (M. pernambucana); the hairy-podded mimosa (M. asperata); the slow American sensitive plant (M. pigra); the glaucous mimosa (M. glauca); the horned mimosa, or cuckold tree (M. cornigera); the horrid mimosa (M. horrida); the Farnesian mimosa, or sponge tree (M. farnesiana); the Egyptian mimosa (M. nilotica); the whorled-leaved mimosa (M. verticillata); the rough tree mimosa (M. arborea); the Lebbeck, or Egyptian mimosa (M. lebbeck); the broad-podded mimosa (M. latisiliqua); the tamarind-leaved American mimosa (M. tamarindifolia); the spiral mimosa (M. circinalis); the small-leaved mimosa (M. pennata); the broad-leaved mimosa (M. latifolia); the purple mimosa, or soldier wood (M. purpurea); the netted mimosa (M. reticulata); the climbing mimosa (M. scandens); the myrtle-leaved mimosa (M. myrtifolia); and the sweet-scented mimosa (M. suaveolens.)

Method of Culture.—These plants are all capable of being increased by seed, and some of the sensitive kinds by layers and cuttings, but the first is by much the best method. The seed procured from the nurseries or seed-shops should be sown in pots of light rich mould early in the spring, covering it with fine earth, a quarter of an inch deep, and plunging the pots in the hot-bed; if in a common hot-bed under frames and glasses, managing them nearly in the manner of tender annuals, and when in a bark-bed in the stove little trouble is required. But moderate sprinklings of water should be given; and when the plants are two or three inches high, they should be planted out singly into small pots, preserving the earth to their roots, replunging them in the hot-bed, &c. giving water and occasional shade till they are well rooted, repeating the waterings frequently. The plants should afterwards be continued either in the hot-bed under glasses, or plunged in the bark-bed of the stove, to facilitate their growth, preserve them in vigour, and increase the sensibility of the sensitive kinds; admitting fresh air pretty freely.

It is proper that the perennial sorts, both shrubby and herbaceous, should be kept in the stove all winter, and principally the year round. And they must be frequently removed into larger pots to prevent the roots from getting through the pots, which they are apt to do, and by that means are often destroyed.

The Acacia kinds are the most tender, requiring the stove almost constantly, except a little in the heat of summer, when they must be placed in a warm situation. They should always have a bark hot-bed, and be put in very small pots filled with sandy mould, the heat of the stove being kept up to above temperate; as the leaves of some of them are shed, they have the appearance of being dried when that is not the case.

Where there is not the convenience of a stove, those who are curious to have the plants, may have them in summer, by the aid of a common dung, or tan-bark hot-bed, under frames and glasses, though not in winter; by raising some of the annual, or any of the other kinds, by seed in spring, in a hot-bed under a frame, &c. keeping up the heat of the bed until the middle of June, and continuing the plants always

always under the frame, raising one end of the lights a little, occasionally, in warm days, to admit fresh air; and as they rise in height, raise the frame at bottom, to allow them full room to grow. About Midsummer, or soon after, some of the low spreading kinds may likewise be turned out with balls, or plunged in their pots into a warm sunny border, and covered with large hand-glasses, which may be lifted off occasionally just to view the plants. By these methods, the plants may be preserved through the summer in their sensitive quality, though not in equal perfection to those in stoves; nor can they be preserved alive in winter out of the stove.

The shrubby kinds that afford spreading branches may be laid any time in summer, in pots plunged in the bark-bed, where they then take root, and are ready to pot off singly in the autumnal season.

The sensitive and humble sorts often branch out profusely, so as to furnish plenty of young shoots for cuttings, which should be planted in pots in the summer season, plunging them in the bark-bed, whereby they often readily take root, and form good plants.

These modes should, however, only be practised when seed cannot be procured.

The general culture of all the species is afterwards to keep them always in pots placed in the stove, being plunged occasionally in the bark-bed, especially the spreading sensitive kinds, frequent waterings being given in summer and winter, but considerably the most in the summer season; shifting them into larger pots as they increase in growth. And although most of the sorts will live in the open air in the heat of summer, it is the best practice to expose them but sparingly.

The fourth and fifth sorts are held in high estimation on account of the singular sensibility lodged in their leaves; which, in consequence of being touched or shaken, either by the hand, a stick, or the least wind blowing upon them, the wings of the leaves suddenly close, and the footstalks fall down. The period of time which the leaves, &c. require to recover themselves, after falling from any irritation, are according to the vigour of the plant, the hour of the day, the sereneness of the atmosphere, and the temperature of the heat of the stove, &c. being often from ten or fifteen minutes to an hour or more.

The plants also, every evening, naturally contract themselves, and expand again in the morning. They are all ornamental and curious in their nature.

MIMULUS, in *Botany*, a name borrowed from Pliny, whose plant however could not be the same with Linnæus's American genus. The word is derived from *Mimus*, a masked actor among the Romans, and alludes to the form of the corolla.—Linn. Gen. 323. Schreb. 423. Willd. Sp. Pl. v. 3. 360. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 2. 361. Juss. 122. Brown Prodr. Nov. Holl. v. 1. 439. Lamarck Illustr. t. 523. Gærtn. t. 53. (Cynorrhynchium; Mitch. 3.)—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personatæ*, Linn. *Scrophulariæ*, Juss. and Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, oblong, prismatic, five-sided, five-folded, five-toothed, nearly equal, permanent. *Cor.* of one petal, ringent; tube the length of the calyx; limb two-lipped; the upper erect, cloven, rounded, reflexed at the sides; the lower broader, with three rounded segments, the middle one smallest; palate convex, cloven, protruded from the base of the lower lip. *Stam.* Filaments four, thread-shaped, within the throat, two of them shorter; anthers cloven, kidney-shaped. *Pist.* Germen superior, conical; style thread-shaped, the length of the stamens; stigma ovate, cloven, compressed. *Peric.* Capsule oval, of two cells, opening transversely at the top; partition membranous, contrary to the valves. *Seeds* numerous, small. *Recept.* oblong, affixed to the partition on each side.

Eff. Ch. Calyx five-toothed, prismatic. Corolla ringent; the upper lip folded back at its sides. Capsule with two cells and many seeds.

1. M. *ringens.* Oblong-leaved Monkey-flower. Linn. Sp. Pl. 884. Curt. Mag. t. 283.—Stem erect. Leaves oblong, linear, sessile.—A native of Virginia and Canada, growing in wet places, and flowering in the summer.—*Root* perennial. *Stem* annual, about two feet high, square, jointed, occasionally branched at the base. *Leaves* two at each joint of the stem, opposite, serrated, acutely pointed. *Flowers* solitary, on long, opposite stalks which spring from the joints of the upper part of the stem; they are of a delicate violet colour and without smell. *Seeds* pale straw-coloured, and tipped at each end, according to Gærtner, with a small, prominent, reddish point.—This plant was referred to several different genera by old authors. Linnæus first called it *Mimulus*, assigning the following explanation of the term in his *Philosophia Botanica*, "MIMULUS, *mimus personatus*."

2. M. *glutinosus.* Orange Monkey-flower. Willd. n. 2. (M. aurantiacus; Curt. Mag. t. 354.)—Stem erect, shrubby, round. Leaves sessile, ovato-lanceolate, rather obtuse.—Gathered by Mr. Archibald Menzies in California. It flowers in our greenhouses, to which it is extremely ornamental, during the greatest part of the summer.—*Stem* nearly three feet high, much branched, jointed, viscid. *Leaves* opposite, sessile, serrated, much blunter than in the last species, revolute, smooth above, veiny. *Flowers* very showy, twice as large as those of M. *ringens*, of a beautiful orange colour, on solitary stalks, two at each joint of the stem. The whole plant is glutinous.

3. M. *alatus.* Oval-leaved Monkey-flower. Willd. n. 3. Vahl. Symb. p. 2. 72.—Stem erect, square, winged. Leaves oval, on stalks. A native of North America. It flowers at Kew in July and August.—We know of no figure of this plant, which very much resembles the first species in appearance.—*Stem* simple, smooth, slightly branched at the top, winged with a membrane at each angle. *Leaves* oval, veined, unequally serrated. *Flowers* on axillary, solitary, opposite, square stalks, swelling upwards. *Corolla* but little exceeding the calyx in length.

4. M. *luteus.* Yellow Monkey-flower. Linn. Sp. Pl. 884. Curt. Mag. t. 1501. (Gratiola foliis subrotundi nervosis, floribus luteis; Feuill. Peruv. v. 2. 745. t. 54.)—Stem creeping. Leaves roundish or ovate, on short stalks embracing the stem.—Found originally at Chili by Feuilleé; and lately in California, and at Nootka, by Mr. Archibald Menzies. Dr. Langsdorff also, one of the Russian embassy to China, found it at one of the Fox Islands.—*Stems* creeping in the lower part, angular, thick at the base, the flowering branches ascending. *Leaves* opposite, at the joints of the stem. *Flowers* on solitary stalks, two at each joint, of a bright yellow colour, their throat spotted with red. The whole plant is massy and magnificent, being thickly set with foliage and flowers.

5. M. *gracilis.* Slender Monkey-flower. Brown Prodr. Nov. Holl. v. 1. 439.—Very smooth, erect. Leaves oblong, somewhat linear, obtuse, nearly entire. Flower-stalks elongated.—Found by Mr. R. Brown near Port Jackson, as well as in the tropical part of New Holland.

6. M. *repens.* Creeping Monkey-flower. Brown Prodr. Nov. Holl. v. 1. 439.—Smooth, creeping. Branches ascending. Leaves oval, obtuse. Flower-stalks shorter than the

the calyx.—Native of New South Wales and Van Diemen's Land. *Brown.*

Mimulus, in *Gardening*, comprehends plants of the herbaceous flowery ornamental kind, of which the species cultivated are, the oblong-leaved monkey-flower (M. ringens); the wing stalked mimulus (M. alatus); and the orange monkey-flower (M. aurantiacus).

Method of Culture.—This is a plant which is very hardy in respect to cold, but should have a loamy soft soil, rather moist than dry, and not too much exposed to the sun.

In the first sort the plants may be increased by parting the roots, not too small, and planting them in autumn, or the early spring, but the former is the better season. It may also be raised by seeds, which should be sown in autumn, soon after they become perfectly ripe, on a border exposed to the morning sun. And the second sort may likewise be increased in the same manner.

With respect to the third kind, it is best propagated by planting cuttings of the young shoots or branches in the early spring in pots of fresh mould, plunging them in a mild hot-bed, being afterwards managed as the other sorts.

The first and the second sort may be introduced in the borders and clumps, and the third among other potted plants of the less tender kinds.

MIMUSOPS, in *Botany*, so called by Linnæus, who seems to have taken the idea of the name from Hermann's *Museum Zeylanicum*, p. 23. This tree is there called *Munamal*, *Muna* being said to signify the human face in the Cingalese language, because the flowers have somewhat of the resemblance of a human face, of which however we seek in vain for any trace in the plates of authors. As this author says the highly fragrant flowers are worn by young women to adorn the neck and head, may not the above appellation allude to their being used as an ornament for the face?—Linn. Gen. 190. Schreb. 252. Willd. Sp. Pl. v. 2. 325. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 349. Brown Prodr. Nov. Holl. v. 1. 530. Juss. 152. Lamarck Illustr. t. 300. Gærtn. t. 42. (Imbricaria; Juss. 152. Binectaria; Forsk.)—Class and order, *Octandria Monogynia.* Nat. Ord. *Holoraceæ*, Linn. *Sapotæ*, Juss. and Brown.

Gen. Ch. *Cal.* Perianth inferior, of eight deep segments in two rows, ovate, acute, coriaceous, permanent. *Cor.* of one petal, wheel-shaped, its segments in two rows, numerous, oblong, entire or divided, the length of the calyx. *Stam.* Filaments eight, awl-shaped, hairy, very short; anthers oblong, erect, as long as the calyx. *Pist.* Germen superior, roundish, rough; style cylindrical, smooth, the length of the corolla; stigma simple, very blunt. *Peric.* Berry of one cell, oval, pointed. *Seeds* one or two, oval, hard.

Obs. Mr. Brown describes an equal number of abortive filaments, alternate with the stamens, and the calyx as in some instances six-cleft. The germen has originally six or eight cells. Dr. Roxburgh also found the abortive filaments.

Ess. Ch. Calyx of eight segments in two rows. Corolla of one petal, in numerous segments, in a double row. Berry with one or two seeds.

1. M. *Elengi.* Linn. Sp. Pl. 497. Fl. Zeyl. 57. Roxb. Coromandel. v. 1. t. 14. (Elengi; Rheed. Hort. Mal. v. 1. 33. t. 20.)—Leaves alternate, remote, ovate, pointed.—A native of sandy places in the East Indies, and much cultivated for its highly fragrant blossoms, which expand chiefly in the hot season. These flowers are sacred to the Hindoo gods. The *root* of this tree is thick and fixed deeply in the earth. *Trunk* branched, many feet in circumference, covered with a brown and smoothish *bark.* *Leaves* alternate, on short stalks, somewhat drooping, waved, very firm, of a deep shining green, three or four inches long and about half as broad. *Flowers* stalked, two or three at the base of the leaf-stalks, slightly drooping, white or yellowish, very fragrant. *Seed* compressed, shining, chesnut coloured. The wood of this plant is said by Rheede to be remarkaby durable in water, but on the contrary very subject to become rotten if exposed to the air.

2. M. *parvifolia.* Brown Prodr. Nov. Holl. v. 1. 531.—A native of the tropical part of New Holland.—Leaves oval, pointed, smooth on both sides. Flower-stalks one to three, downy, longer than the downy leaf-stalks.—All that we know of this species is from its discoverer Mr. Brown, who says that it is very nearly allied to *M. Elengi*, but that the flower-stalks of the latter are more numerous, and shorter than the leaf-stalks, which are smoothish.

3. M. *Kauki.* Linn. Sp. Pl. 497. Fl. Zeyl. 57. Brown Prodr. Nov. Holl. v. 1. 531. Willd. n. 3. (Metrosideros macassarensis; Rumph. Amboin. v. 3. t. 8.)—Leaves on shortish stalks, crowded together at the ends of the branches, ovate, obtuse, silvery beneath.—A native of the East Indies and Arabia, as well as of the tropical parts of New Holland.—The *branches* of this tree are thicker than those of *M. Elengi*, having small scars scattered all over them. *Leaves* crowded together at the ends of the branches. *Flowers* very similar in structure, but larger than those of the first species.—The *berries* are eaten in their crude state by the natives of Macassar, and are said to have a pleasant flavour. The foliage is extremely ornamental, and the wood useful for the handles of tools and such purposes.—Mr. Brown hazards a doubt whether the *Manil-kara*, Rheed. Hort. Mal. v. 4. t. 25, can possibly be cited as a synonym of *M. Kauki* on account of its six-cleft flowers, though they agree precisely as to foliage.

4. M. *hexandra.* Willd. n. 2. Roxb. Coromandel. v. 1. t. 15.—Leaves alternate, obovate, emarginate. Flowers hexandrous.—Native of the East Indies, in the mountainous, uncultivated parts of the Circars. It flowers towards the beginning of the wet season.—The *trunk* of this large tree is erect, and much branched, with an ash-coloured *bark.* *Leaves* alternate, on stalks, wedge-shaped, deeply emarginate, very hard, of a deep shining green, three to five inches long, and about a third as broad. *Flowers* several together, axillary, stalked, variegated with white, lilac and yellow. *Berry* the size and shape of an olive.

5. M. *Imbricaria.* Willd. n. 5. (Imbricaria; Juss. et Lamarck Illustr. t. 300.)—Leaves crowded together at the ends of the branches, ovate, obtuse, retuse. Berry with many seeds.—A native of the Isle of Bourbon.—We are inclined to believe that this is very near *M. Kauki*, or perhaps a variety of that species, although we have adopted it on the authority of Willdenow.

MINA, μνᾶ. The Attic mina was either nummary or ponderal; in the first acceptation it was the sixtieth part of a talent, and contained a hundred drachmæ, or denarii, amounting in our coin (if we allow nine-pence for the value of the drachma), to three pounds fifteen shillings. The mina of Athens contained, at first, seventy-three drachmæ; but Solon gave it a hundred. Mina, considered as a weight, was also divided into a hundred drachmæ. It was regarded as a pound weight of the country to which it belonged; and the Attic pound is considered as the same with the Roman, and very nearly one pound troy. See Drachm.

Mina was also a medicinal weight, consisting of twelve Roman ounces; but as in coinage eight drachms were allowed to the ounce, the mina, or pound, contained ninety-six, *i. e.* the

the pound in weight consisted in fact of ninety-six drachmæ, while the pound in tale had a hundred. Dr. Arbuthnot asserts that the common Attic pound contained sixteen ounces, and was equal to our pound avoirdupoise; but this assertion seems to be contradicted by ancient testimony. See COIN and WEIGHT.

MINA, or *Mine*, in *Commerce*, a corn measure of Genoa, equal to 8 quarte, or 96 gombette: 100 English quarters = 233 mina, and a mondino of salt = 8 mine. See MEASURE.

MINA, in *Geography*, a town of Algiers; 50 miles S.E. of Oran.—Also, a river of Algiers, which runs into the Sheliff, 12 miles E. of Mustygannim.

MINA, or *Minau*, a sea-port town of Persia, in the province of Kerman, at the entrance of the gulf of Persia, at the mouth of the river Ibrahim, the air of which is insalubrious. It is surrounded with walls, and defended by towers, and has medicinal springs and baths; 42 miles W. of Ormus. N. lat. 27° 8′. E. long. 56° 40′.

MINADA, a town of Japan, in the island of Niphon; 20 miles N. of Xenday.

MINADAH, a river of Bengal, which runs into the Ganges at its mouth, N. lat. 22° 45′. E. long. 91° 3′.

MINAES GERAES, a jurisdiction of South America, in Brazil, situated between the 15th and 22d degrees of S. lat., and the 25th and 33d degrees of W. long. The number of inhabitants is computed to be about 35,180 whites, 26,075 Indians, and 108,400 slaves. The fifth part of the gold found in this jurisdiction, and formerly paid to the king of Portugal, is estimated yearly to be about five millions of livres.

MINAGGNHINIM, a pulsatile instrument of music among the Hebrews, which was a square table of wood, fitted with a handle; over this table was stretched an iron chain, or hempen cord, passing through balls of wood or brass, which struck against the table when the instrument was shook, and occasioned a clear sound, which might be heard at a great distance.

MINARES, in *Geography*, a river of Spain, which waters the province of Aragon.

MINAS, *Basin of*, or *Les Mines* bay, sometimes called "Le Grand Praye," a gulf on the S.E. side of the bay of Fundy, into which its waters pass by a narrow strait; about 30 leagues from the entrance of Annapolis, and ten from the bottom of Bedford bay; 12 leagues in length and three in breadth.

MINAS, or *De las Minas* hill, the middlemost of the three hills, serving as inland marks for Bonaventura bay and river, on the coast of Peru, in South America; S. of Panama bay. N. lat. 3° 20′. W. long. 75° 18′.

MINAS *des Rixas*, a town of Brazil, in the government of Goya; 85 miles N. of Villaboa.

MINASCOU BAY, a bay in the river St. Mary, between lake Superior and lake Huron; containing several islands. N. lat. 46°. W. long. 84°.

MINATO, *Count* NICOLA, of Bergamo, in *Biography*, a dramatic poet of great fertility. The reputation which he had acquired in writing for the theatres of Venice, occasioned his being engaged at Vienna as imperial poet laureate. He furnished the emperor's lyric theatre with a great number of serious operas, and still more small occasional dramas and poems for music. On every birth-day and occasion of joy and festivity, an analogous piece or two, besides the fixed operas for winter and autumn. These operas passed into Italy, where they were new set and performed with success. This poet possessed a perfect knowledge of history, his fable was generally well planned, and his characters well sustained. He had genius and invention, and gave good opportunities for decoration and machinery. He flourished from about 1650 to 1683.

MINATTA, *Isle la*, in *Geography*, lies on the N. coast of lake Superior, in Upper Canada, near to, and E. of, the grand Portage, extending to Thunder bay.

MINAYA, a small town of Spain, in the province of La Mancha: it was formerly considerable, but is now almost reduced to the size of a village. The entrance to the parish church, which is of a moderate size, and has three chancels, is through a portico supported by two pillars of the Corinthian order, of white marble; 2½ leagues from La Roda.

MINAZZO, CAPE, a cape of Spain, on the W. coast of Galicia. N. lat. 42° 51′. W. long. 9° 20′.

MINCA, a name given by the ancients to a very coarse and bad kind of myrrh.

MINCH, in *Geography*, a channel of the North sea, between the Hebrides and the main land of Scotland.

MINCHA, in the *Jewish Customs*, offerings of meal, cakes, or biscuits, made in the temple of the Lord. The Seventy have sometimes preserved this word in their translation; but instead of *mincha* they read *manaa*, which doubtless was the received pronunciation in their time. We find *manaa* in the same sense in Baruch, i. 10. Levit. ii. 3, &c. See the Greek of Jerem. xvii. 26. Dan. ii. 46. 2 Kings, viii. 5. 9. xvii. 7. xx. 12. 2 Chron. vii. 7. Nehem. xiii. 5, 9, &c. Calmet. Dict. Bibl.

MINCHIN-HAMPTON, in *Geography*, a market-town in the hundred of Longtree, and county of Gloucester, England, is situated on the declivity of a gentle eminence, and consists of four irregular streets, intersecting each other at right angles. The chief trade of this town is a manufacture of cloths, which is carried on to a considerable extent, the many brooks and rivulets in the vicinity being extremely favourable for the purpose. The church, which is built in the form of a cross, was founded by the nuns of Caen, in the reign of Henry III. Numerous monuments and sepulchral inscriptions diversify the interior of this fabric; and in the church-yard appears a brass plate, in honour of Mr. James Bradley, the celebrated astronomer, who was a native of Gloucestershire, and died in 1762. Here are three market-houses, two of which were erected by P. Sheppard, esq. in the year 1700, with the view of establishing a wool-market, but the design failed of success. Here is likewise a respectable free-school. Leland says "there were nunnes" in this town; and Camden and Speed hence affirm it contained a nunnery. Bishop Tanner, however, considered this statement as erroneous, and says, "this place was called Minchin-Hampton, only because the manor was given to the nuns, or minchins of the Holy Trinity, at Caen, in Normandy, by William the Conqueror." The abbess of that monastery purchased for it the privilege of a weekly market, which continues to be held on Tuesday. According to the parliamentary returns of 1801, this town contained a population of 3419 persons, of which number 1549 were males, and 1870 females. To the west of this town lies an extensive common, called Amberley, remarkable for being the scite of a very singular encampment. The great vallum of this work is irregular, and has smaller trenches branching from it. It extends nearly three miles in length, to a spot called Woeful-Dane-Bottom, probably in memory of some signal defeat sustained here by that people, whom Mr. Fosbrooke conjectures to have occupied this camp as a summer residence, during their abode at Cirencester in the year 879. At Rodmarton, a small village near the foss-way, which passes through this district, a tessellated pavement and other Roman remains were discovered about the

the middle of the feventeenth century. Horfley, a difufed market-town, two miles from Minchin-Hampton, contains fome fragments of a priory, formerly dependent on the monaftery of St. Martin's, at Trours, in Normandy. In a field adjoining to Gatcombe park, the feat of Philip Sheppard, efq., is a large oval tumulus, now planted with firs, which had erect ftones at each end of it. On its fummit is placed a huge fragment of rock, evidently a fepulchral monument, which has been long diftinguifhed by the appellation of Tingle-ftone. At fome diftance from this tumulus appear two large ftones, fet upright in the ground; one has its top broken off, but the other is perfect, and rifes ten feet above the furface. Tradition affigns one or both of thefe memorials to Long, a Danifh chieftain, whence comes the name Long's ftone, or pillar. Bigland's Hiftory of Gloucefterfhire, vol. ii. folio. Beauties of England and Wales, vol. v.

MINCHIVAVIDA, a fmall ifland in the South Pacific ocean, near the coaft of Chili. S. lat. 44° 40'.

MINCIO, a river of Italy, which rifes in lake Garda, forms the lake which furrounds the city of Mantua, and afterwards runs into the Po near Sachetta.—Alfo, a department or divifion of the new kingdom of Italy, confifting of what was before the revolution the duchy of Mantua, containing 123,649 inhabitants, who elect nine deputies. The capital is Mantua.

MIND, Mens, denotes a thinking or underftanding being. See Spirit.

Philofophers generally allow three kinds of minds, *viz.* *God*, *angels*, and the human *foul*. For a thinking being muft either be finite or infinite: if infinite, it is *God*; and if finite, it is either joined with a human body, or not; if the latter, it is an *angel*; if the former, a *foul*.

The *human mind* is properly defined a thinking rational fubftance; by *thinking* it is diftinguifhed from body; and by *reafoning* from God and angels, who are fuppofed to fee and know things intuitively, without the help of deduction and difcourfe.

Mind, *Affection of the.* See Affection.

MINDANAO, or Magindanao, in *Geography*, one of the Philippine iflands, and interior only to Luçon in extent: it is of a triangular form, and in circumference about 900 miles, but fo interfected with promontories and bays, that a perfon might crofs it in a day and a half. It was difcovered by the Spaniards who accompanied Magellan. It lies S.E. of Manila, at the diftance of 600 miles. Although mountainous, the vales confift of a rich black mould, watered with the fineft rivulets; it furnifhes ample fupplies of rice, and alfo palm-trees, the pith of which affords fago, and this, when reduced to meal, is ufed for making bread and bifcuit throughout all the ifland. It has a variety of fruits in common with the other iflands of this archipelago; but the cinnamon is peculiar to itfelf, and the trees that furnifh it grow on the mountains without culture, and without being regarded as the property of any individual. By digging deep in the ground, and fearching the rivers, the inhabitants find good gold. They alfo collect plenty of fulphur from the burning mountains. The fcenery of Mindanao is beautiful, and it is fertile in a variety of productions. The chief Spanifh fettlement is at Sambuang, in the S.W. The "Lano" is a large inland lake, about 60 miles in circumference: horfes and buffaloes have multiplied here to a furprifing degree. In the fouth, there is a volcano of conftant eruption, which ferves as a fea-mark. In the ftrait between this ifland and that of Xolo, very large pearls are found. N. lat. 5° 40' to 9° 55'. E. long. 122° to 126° 27'.

MINDAY, a town of Pegu; 8 miles S. of Prome.

MINDELHEIM, a town of Bavaria, and capital of a lordfhip, about 8 miles fquare; 22 miles S.W. of Augfburg. N. lat. 48° 2'. E. long. 10° 27'.

MINDEN, a principality of Germany, in the kingdom of Weftphalia, about 96 miles in circumference, confifting of good corn land, fo that agriculture is carried on with great diligence and with fuch fuccefs, that from hence neighbouring countries are fupplied with flax and corn, and particularly with wheat and barley. This principality has alfo wood, turf, coal, and a productive falt-work, and plenty of fifh. The Roman Catholics only enjoy in the town of Minden, and the Calvinifts every quarter of a year, at the citadel of Peterfhagen, their public worfhip; all other churches in the country belong to the Lutherans. This principality is now annexed to the kingdom of Weftphalia.

Minden, a city of Weftphalia, and capital of the forementioned principality, and formerly one of the Hanfe towns, is fituated on the Wefer. It is about two miles in compafs, and furrounded with walls and ramparts. Its fituation for commerce is advantageous, and fome of the inhabitants carry on a confiderable brewery; others are employed in agriculture and breeding of cattle. The cathedral is a confiderable building, and the chapter confifts of 18 perfons, partly Roman Catholic and partly Lutheran. This town was an important place, even in the reign of Charlemagne; and it has fince been contended for, and occafionally poffeffed by the Imperialifts, Swedes, and French; 30 miles E. of Ofnabruck. N. lat. 52° 18'. E. long. 8° 56'.

Minden, a poft-town of America, in Montgomery county, New York; 472 miles from Wafhington.

MINDEPILLY, a town of Hindooftan, in Myfore; 8 miles W. of Veniatighery.

MINDERER, Raymond, in *Biography*, a phyfician of Augfburg, who was diftinguifhed in the early part of the feventeenth century as a partizan of the chemical fect. He was alfo eminent as a military phyfician, in which capacity he ferved feveral campaigns, with univerfal efteem throughout all ranks in the army; whence he alfo rofe to high reputation and practice in the courts of Vienna and Munich, and was confulted by the principal nobility. He publifhed the refult of his experience relative to the difeafes of armies, in the German language; and this work was tranflated into Latin, with the title of "Medicina Militaris, feu, Liber Caftrenfis, euporifta et facilè parabilia Medicamenta continens," Vienna, 1620, 8vo. This work was feveral times reprinted, and was alfo tranflated into Englifh in 1674. He was likewife author of the following works. "De Peftilentiâ Liber unus," ibid. 1608. "Aloëdarium Marocoftinum," ibid. 1616, and afterwards republifhed. "De Calcantho, feu Vitriolo, ejufque qualitate, virtute, et viribus," 1617. "Threnodia Medica, feu, Planctus Medicinæ lugentis," 1619. His chemical reputation is evinced by the connection of his name in the fhops, even at this day, with the neutral falt, the acetate of ammonia, which is called Mindererus' fpirit. Eloy. Dict. Hift.

MINDERERI Spiritus. See Vinegar.

MINDIGAUT, in *Geography*, a town of Hindooftan, in Dooab; 5 miles S.E. of Canoge.

MINDIUM, in *Botany*, Juff. 164. Medium Diofcoridis, Mindium Rhazis; Rauw. It. 284. See Medium and Michauxia.

MINDO, in *Geography*, a town of South America, in the audience of Quito; 20 miles N.W. of Quito.

MINDORO, one of the Philippine iflands, about 27 miles S. from the ifland of Luçon, triangular in figure, and about 150 miles in circumference. It is high and mountainous,

mountainous, abounding in cocoa and other fruit-trees, with some rice. A part of the sea adjoining this island is called the "sea of Mindoro." N. lat. 12° 21′ to 13° 30′. E. long. 120° 24′ to 121° 24′.

MINDOWLY, a town of Hindoostan, in the circar of Singrowla; 10 miles N. of Soipour.

MINDYGUR, a town of Hindoostan, in Oude; 5 miles S. Canage.

MINE, a town of Abyssinia; 170 miles S.W. of Gondar. N. lat. 0° 4′. E. long. 35° 30′.

MINE. This word is applied generally to all works carried on under ground, but seems principally to belong to such as have for their object the discovery and production of the metallic ores.

The construction of the works in various mines differs according to circumstances, such as the form of the hills in which they are situated, or the position of the ores, whether found in veins or beds. Some mines are formed by a level or drift entering the foot of a mountain, and extending to the deposits of metal within it, which may be taken away and carried out through this opening; and in this case *shafts* are only required for the purposes of ventilation.

This seems to be the simplest state of mining, and is, as well as such mines as have been formed by following ore from the surface to such depths as water would permit, to be ranked among the earlier efforts of this kind.

The more extended operations of mining are to be found where regular metallic veins, situated in primitive rocks, are worked to great depths below the level of the sea, where perpendicular *shafts*, drained of the constantly accumulating water by engines, form the means of communication from the surface to *levels* driven upon the *lode* or vein, at various and successive depths, so as to open all parts of it for the discovery of its contents.

A mine thus constructed, of any considerable extent, is one of the most extraordinary instances of human enterprize, patience, and ingenuity; especially if it be considered that its formation depends upon the application of two of the most wonderful discoveries on record, the expansive forces of gunpowder and steam.

Mines in Cornwall and Devon are generally worked by a company of proprietors, called adventurers, who agree with the owner of the land, or lord of the soil, as he is usually denominated, to work the mine for a certain term of years, paying him, by way of rent, a proportion of the ores raised, or an equivalent in money. The grant thus made to the adventurers is called a *set*, and the lord's rent, if paid in ore, is called the *dish* (probably from the ancient practice of measuring it by a vessel of that sort), and when settled for in money, has the term *dues* applied to it.

The adventurers divide their undertaking into shares of different magnitude, but usually forming in the whole some even and easily divisible number. The smallest share usually held by one adventurer is one sixty-fourth part, though in some large mines this share is divided, and a person may then have only a one hundred and twenty-eighth part of the whole, while others may hold eighths, others sixteenths or thirty-seconds, and some larger proportions, but the whole added together make up sixty-four shares. Any part of the concern held by one person is generally called a *dole*, and distinguished as to its relation to the whole by adjoining to this word the denomination of its value, as an eighth dole, a sixteenth dole, &c.

Mines in Cornwall and Devon are usually named as soon as they are undertaken, and this practice seems to have been of considerable antiquity, as the word *wheal*, or *huel*, usually even now prefixed to these appellations, is derived from the ancient Cornish language, and signifies a work or mine. The other parts of the names of mines often relate to the situation, or have been given in compliment to some person connected with them, or adopted according to the fancy of the adventurers. Thus Wheal Rose is probably derived from the Cornish word *ros*, a valley, and means therefore the mine in the valley; Wheal Godolphin has the name of a family; and among the arbitrary appellations which are the most numerous, may be instanced Wheal Unity, Wheal Virgin, Wheal Jewel, &c.

The *bounds*, or limits of the set of a mine, are usually marked out upon the surface, and include the space of ground in which any company of adventurers have contracted for the right working. Bounds for working tin are recognized by the stannary laws of Devon and Cornwall, as a property in themselves distinct from the possession of the soil, and were probably originally granted to encourage the search for this metal by the laws of the duchy, that the revenue of the chief lord might not suffer by the unwillingness of the possessor of the soil to have its surface disturbed. Tin bounds that have been legally renewed, or possession retained, are even now in their original state in this respect; but copper mines, and also many tin mines, are now generally held of the possessor of the fee.

Mines are generally conducted in Cornwall and Devon by a manager appointed by the adventurers, who hold meetings at the counting-house to revise and pass the accounts, and to debate and determine on all subjects relative to the prosecution of the works submitted to them.

Under the principal agent others are appointed, who are practical miners, and who superintend the various operations and settle the terms of the contracts with the workmen, which are made by a kind of public auction. These agents are called *captains*, and the number employed in a mine is in proportion to its extent and importance. Some attend principally to the works below, and are therefore called *underground captains*; others take charge of the operations on the surface, and are therefore distinguished by the appellation of *grass captains*. It would be injustice to this useful and respectable body of men to pass them over without noticing the intelligence, activity, and skill by which the agents of the mines in the districts alluded to are distinguished.

The establishment of a mine further includes occasionally an engineer, a head carpenter and smith, who have each their workmen under their care; a *pitman*, who directs the fixing and repair of the pump-work; a *timberman* or *binder*, who superintends the construction of the woodwork under ground, for securing the shafts, ladders, levels, and so on: and besides these operative men, there are usually clerks to keep the accounts, and persons to receive and deliver to the workmen the materials used in their operations.

The miners working under ground are divided into two classes, according to the mode by which they are paid. Those of the first class are called *tributers*, who work on the productive parts of the mine, and receive a proportion of the ore which they procure and make merchantable, for their labour. This mode of payment, by its occasionally leading to unusual profit, stimulates to great exertion in the discovery of fresh deposits of ore, and is therefore conducive to the interests of the employer as well as the workman. To the reward thus held out to skill and intelligence, may probably be attributed the prevalence of these qualities, which may be observed more particularly in this class of Cornish miners. The other workmen employed under ground are denominated *tutwork-men*, who agree for sinking shafts, driving levels, and so on, at a certain price *per* fathom. These prices are exceedingly various, as the rock to be penetrated differs in degrees

grees of hardness, or the nature of the work exposes the men to more or less danger or inconvenience from water or bad air.

The people employed on the surface in dressing the ores, generally perform their labour by task-work, the amounts being charged to the account of the tributers, whose ore is undergoing this process.

The copper ores, when ready for sale, are sampled by agents of the smelting companies, who visit the mines for that purpose, and are sold on a fixed day by a public sale, called a *ticketing*, and afterwards weighed and carried to a port and shipped to Wales, where the copper smelting houses in general are. Tin ores are smelted in Cornwall, and are sold by the miner to the owners of the smelting houses by private contract, valuing them by an assay made by the buyer. In this respect the value of tin ores is determined by a mode much more uncertain and irregular than that employed for copper, the assay of which is conducted with extreme care, and wonderful accuracy.

The extent of the returns and costs of the mines in Cornwall and Devon, both collectively and separately, may be seen by referring to the history of mining in this district, where the tables of the state of these concerns exhibit a very interesting picture of the great increase of these extensive undertakings. See MINING, *History of*.

The king by his prerogative hath all mines of gold and silver to make money; and therefore those mines, which are properly royal, and to which the king is entitled when found, are only those of silver and gold. (2 Inst. 577.) By the old common law, if gold or silver be found in mines of base metal, according to the opinion of some, the whole was a royal mine, and belonged to the king; though others say that this was only the case, when the quantity of gold or silver was of greater value than the quantity of base metal. (Plowd. 336.) But by statute no mines of copper, tin, iron, or lead, shall be adjudged royal mines, though gold or silver be extracted. (1 W. and M. c. 30.) And persons having mines of copper, tin, lead, &c. shall enjoy the same, although claimed to be royal mines; but the king, or persons claiming royal mines under his authority, may have the ore (except tin-ore in Devon and Cornwall) paying to the owners of the mines, within thirty days after it shall be raised, and before removed, 16*l. per* ton for copper-ore washed, and made merchantable; for lead-ore 9*l. per* ton; tin or iron, 40*s.* &c. (Stat. 5 W. & M. c. 6.) If any person maliciously set on fire any mine, or pit of coal, he shall be guilty of felony, without benefit of clergy, by stat. 10 Geo. II. c. 32. If any person shall wilfully or maliciously set fire to, burn, demolish, pull down, or otherwise destroy or damage any fire-engine, or other engine erected for draining water from coal mines, or for drawing coals out of the same; or for draining water from any mine of lead, tin, copper, or other mineral, or any bridge, waggon-way, or trunk erected for conveying coals from any coal mine, or staith for depositing the same; or any bridge, or waggon-way erected for conveying lead, tin, copper, or any other mineral, from such mine, or cause the same to be done, he shall be guilty of felony, and transported for seven years. (9 Geo. III. c. 29.) Provided that no person be prosecuted under this act beyond 18 months after the offence committed. By 39 & 40 Geo. III. c. 77, destroying or damaging mines or roads leading to or from the same, &c. incurs the guilt of misdemeanor, and any one person so offending may, on conviction, be imprisoned for any time not exceeding six months. Colliers and miners working in a manner contrary to their agreement, or not fulfilling their contracts, shall, on conviction, forfeit not exceeding 40*s.* and on non-payment be imprisoned for a time not exceeding six months, or until the penalty and costs shall be paid. Stealing ore out of mines is no larceny, except only those of black-lead, the stealing ore out of which is felony, punishable with imprisonment and whipping, or transportation not exceeding seven years, and escaping from such imprisonment, or returning from transportation is felony, without benefit of clergy, by 25 Geo. II. c. 10.

MINE-*adventurers, Company of*, had its first rise about the year 1690, when certain mines of lead and copper were found in South Wales, which were divided by the proprietors into twenty-four shares; and in 1693 sub-divided into four thousand and eight shares, for the term of twenty-two years and a half; to which term five years more were added in 1698, and the affairs of the company regulated by a new constitution. In 1704, queen Anne granted a charter of incorporation to this company; in consequence of which several new shares were added, so that the whole number amounted to six thousand and twelve. However, the interests of this corporation were so ill managed, that the proprietors and creditors petitioned parliament in 1710, and a committee of the house of commons was appointed to enquire into its state. The result of the enquiry was a censure on the principal managers; and though, in 1711, a law was passed for the better regulation of the company, and the relief of the creditors and proprietors, nothing could preserve it from sinking.

MINE, in the *Art of War*, denotes a subterraneous canal or passage dug under the wall or rampart of a fortification intended to be blown up by gunpowder.

The passage of a mine leading to the powder is called the *gallery*. These passages or galleries made within the fortification, before the place is attacked, and from which several branches are carried to different places, are generally four feet wide, and five feet high, and the earth is supported from falling in by arches and walls, as they are to serve for a considerable time; but when mines are to be used in a short time, the galleries are only about three feet wide and five high, and the earth is supported with wooden frames or props. When the gallery is carried on to the place where the powder is to be lodged, called the *chamber*, the miners make this generally of a cubical form, large enough to hold the wooden box, which contains the powder necessary for the charge; this box is lined with straw and sand-bags, to prevent the powder from contracting any dampness. The chamber is sunk somewhat lower than the gallery, unless the besieged can raise the water in the ditch, and incommode the gallery; in which case the chamber is made higher than the gallery, that the water may not be let in and spoil the mine. The line, drawn from the centre of the space containing the powder, perpendicular to the nearest surface, is called the line of *least resistance;* the pit or hole, made by a mine when sprung, is called the *excavation*. The fire is conveyed to the mines by a pipe or hose, made of coarse cloth, whose diameter is about an inch and a half, called *saucisson*, extending from the chamber to the entrance of the gallery, to the end of which is fixed a match, that the miner who sets fire to it may have time to retire before it reaches the chamber. In order to prevent the powder from becoming damp, the saucisson is laid in a small trough, called *auget*, with straw in it, and round the saucisson, with a wooden cover nailed upon it. There are various kinds of mines, which acquire different names; as *royal* mines, *serpentine* mines, *forked* mines, as their passages are straight, oblique, winding, &c. The mines made by the besiegers in the attack of a place are simply called *mines*, and those made by the besieged *counter-mines*. They are both made in the same manner, and for the like purposes, *viz.* to blow up their enemies and their works; only the principal galleries and mines of the besieged are usually made before

before the town is besieged. The besieged generally make a great many small mines under the glacis, of about six, seven, or eight feet deep under ground, which are called *fougasses* or *fougades*. They make likewise another sort, called *coffers* or *caissons*, which are a kind of wooden boxes three or four feet long, and a foot or eighteen inches wide, which they bury four, five, or six feet under the glacis, and about four yards distant from each other.

Mines, *History of*. It is observed by writers on this subject, that mines were in use long before the invention of gunpowder; for the ancients made galleries or subterraneous passages under the walls of places, and supported them with strong props; filling the interval with all kinds of combustibles, which being set on fire burnt their props, and, the walls being no longer supported, fell, whereby a breach was made. The besieged also made use of similar passages from the town under the besiegers' machines, with which they battered the walls, in order to destroy them. But the art of mining has received great improvements since the invention of gunpowder. The first mines which we read of, since the discovery of gunpowder, were used, in 1487, by the Genoese, in the attack of Serezanella, a town belonging to Florence: however, as these failed, they were neglected for a considerable time. The first successful application of the blowing of mines in sieges was in the kingdom of Naples, in the year 1503; when Pietro de Navarre by this means possessed himself of a fort garrisoned by the French. But the first celebrated use of these mines in opposing the progress of the besiegers was in the years 1666, 1667, 1668, at the siege of Candia; though they had been often practised in the defence of places before, in a less memorable manner; for by the assistance of this invention principally, the city of Candia kept the whole power of the Ottoman empire at bay for three years successively. Since that time the advantage of counter-mines hath been better understood. The last eminent instance of their great utility was in the defence of Turin, in 1706: for so effectually were the besiegers traversed thereby, that, after near four months of open trenches, they were not in possession of more than the counter-scarp, and even then, eleven pieces of their cannon were blown up by the defendants but three or four days before the place was relieved.

The first professed writer on mines was the celebrated M. Vauban; he was succeeded by M. de Valliere, one of the greatest masters in the art of mining; who, uniting theory with experiment, discovered, by measuring several excavations, that the pit or hole made in the earth, when the mine was sprung, was not an inverted cone (*Plate* VI. *Fortification*, *fig.* 10.) nor a frustum of a cone (*fig.* 11.) as Vauban and others had supposed, but nearly a paraboloid (*fig.* 12.); and his tables were computed according to that figure. It has been generally admitted by miners, that the diameter of the pit or hole made by the mine was always twice the line of the least resistance, and that this diameter should never exceed this proportion. But M. Belidor undertook to remove this prejudice; and however generally it may still prevail, he seems to have proved by many experiments, which have since been repeated by others, that the diameter of the hole made by a mine may be increased to any length in regard to the depth of the mine.

Mines, *Theory of*. The estimation of the proper quantity of powder with which a mine is to be loaded in any kind of soil, or at any depth under ground, in order to produce any proposed effect, is the most difficult part of the whole art of mining. This depends not only on the quantity of earth to be blown up, but likewise on the tenacity of the different soils in which the mines are made. The quantity of earth to be raised depends on the figure of the excavation; for if this is known, the solid content may be determined by geometry; and by weighing exactly a cubic foot of that soil, we can easily discover what weight is to be raised; and by knowing what quantity of powder is required to raise a certain weight, the tenacity of the parts may also be had, by making a mine so as to produce a good effect; and subtracting the quantity of powder, necessary to raise the weight of the solid from the charge of the mine, the remainder would be the quantity necessary to overcome the tenacity. It is, however, disputed, as we have already observed, what the figure of the excavation is: it was at first imagined to be an inverted cone, as A C B (*fig.* 10.) whose vertex is in the centre of the chamber, and the radius of its base A D equal to its axis C D; but this being found to allow too small a charge, it was next supposed to be a frustum of a cone, as A E F B (*fig.* 11.) whose lesser base E F is equal to the line C D of least resistance, and the greater A B equal to twice that line. On this last supposition, said to be confirmed by the experiments of M. Maigrigny, under M. Vauban, near Tournay, miners have computed their tables of the quantities of powder necessary for charging mines at different depths.

However, Mr. Belidor disputed the conclusions of Maigrigny; whose experiments were examined by direction of the chief commander of the artillery of La Fere, in the construction of more than a hundred and fifty mines between the years 1725 and 1730. In the course of this enquiry, seven mines were made, whose line of least resistance was ten feet, and loaded with the following quantities of powder, *viz.* the first with 120lb.; the second with 160lb.; the third with 200lb.; the fourth with 240lb.; the fifth with 280lb.; the sixth with 320lb.; and the seventh with 360lb. These mines being sprung one after another, and their excavations examined, the diameters of their bases were found to be as follow: that of the first $22\frac{1}{3}$ feet; the second, 26 feet; the third, 29 feet; the fourth, $31\frac{1}{4}$ feet; the fifth, $33\frac{1}{2}$ feet; the sixth, 36 feet; and the seventh, 38 feet. These experiments invalidated the principles of Maigrigny; nevertheless miners have still doubted, whether the diameter of the excavation can be made greater than double the line of least resistance, or whether the excavation itself will not become like a well or pit when overcharged. As to the true figure of the excavation, this was discovered by M. de Valliere, and ascertained by others after him to be very nearly a paraboloid, as A E B (*fig.* 12.) having the centre of the powder or charge in the focus C, C D the line of least resistance, A B the diameter, and C A the radius. Mr. Muller, however, observes, that though the figure of the excavation is a paraboloid, the quantity of the earth to be blown up should be estimated by the part A L M B, cut off by a plane L M, passing through the focus or centre C of the chamber, parallel to the horizon A B; the other part L E M being occasioned by the force of the powder pressing downwards; because, he says, the explosion of gunpowder, acting on all sides alike, must condense the solid under the chamber from L to M, by its pressure downwards, so long as it presses the earth above L M upwards; and it cannot be said, that any particle of earth under the horizontal line L M can be drove upwards. In order to find the content of this solid, let $EK = EC = \frac{1}{4}$ of P, or the parameter; and it appears from the well known properties of the parabola, that $AD^2 = ED \times P$; $LM = P$; and $CA = KD$. And in tht right-angled triangle C D A, $CD^2 + DA^2 = CA^2 = KD^2$; and, therefore, $\sqrt{CD^2 + DA^2} = KD$; whence, if C D and D A are given, the line K D, and

and conſequently C K, or its equal C L, will be known; and, therefore, if the line of leaſt reſiſtance C D, and the radius D A of the baſe are given, the parameter may be found. Moreover, the ſolid content of the paraboloid is equal to half the cylinder of the ſame baſe and altitude; if r expreſſes half the circumference, whoſe radius is unity: *i. e.* if $r = 1.57$; then, becauſe $1 : 2r$, or the radius to the circumference as the ſquares of the radii C L, D A, are to the areas of their circles; we have $r\,ED \times AD^2$ for the ſolid content of A E B, and $r\,EC \times CL^2$ for the ſolid L E M; therefore, their difference $r\,ED \times AD^2 - r\,EC \times CL^2$, will expreſs the ſolid required. But if P expreſſes the parameter L M, then will $P \times ED = AD^2$, and $P \times CE = CL^2$, and theſe values ſubſtituted in the expreſſion of the ſolid, give $rP \times ED^2 - rP \times EC^2$: or, becauſe $ED = EC + CD$, and $KD = CD + 2EC$, we ſhall have this expreſſion reduced to $rP \times CD \times KD$. But as r is a conſtant number, it may be neglected in comparing the ſolids; and then $P \times CD \times KD$ will be the expreſſion of the ſolid. And when two excavations are compared together, which have the ſame line of leaſt reſiſtance C D, the ſolid will be expreſſed by the rectangle $P \times KD$. Hence if this ſolid, or the quantity of earth to be raiſed, and the line C D of the leaſt reſiſtance be given, the parameter P may be found; and having the parameter and the line C D, the equation $P \times ED = AD^2$, will give the radius A D of the baſe. For if $CD = c$, and the given ſolid $ALMB = a$, then becauſe $CE = \frac{1}{4}P$, the expreſſion $P \times CD \times KD$ will give

$$Pc \times \overline{\tfrac{1}{2}P + c} = a, \text{ or } PPc + 2Pcc = 2a, \text{ and } PP + 2Pc = \frac{2a}{c}, \text{ to which adding } cc, \text{ we ſhall have } PP + 2cP + cc = \frac{2a}{c} + cc; \text{ and } P + c = \sqrt{\frac{2a}{c} + cc}.$$

In comparing mines together, which have the ſame line of leaſt reſiſtance, the rectangle $P \times KD$ gives $PP + 2cP = 2A$, to which adding cc, we ſhall have $PP + 2cP + cc = 2a + cc$, whoſe ſquare root is $P + c = \sqrt{2a + cc}$. By means of theſe equations, all the different problems relating to mines are eaſily ſolved, on the ſuppoſition, that the forces of powder are proportional to their quantities, and, therefore, the charges alſo proportional to the quantities of earth to be raiſed in the ſame ſort of ſoil, *i. e.* in ſoil of the ſame denſity and tenacity. Some writers, however, aſſert, that the elaſtic force of powder is greater in proportion in larger quantities than in ſmall ones, which Mr. Muller denies; and Mr. Belidor gives another reaſon for diminiſhing the charges of mines, as the earth to be raiſed increaſes; which is, that not only the weight of the earth to be raiſed is to be conſidered, but likewiſe the preſſure of the atmoſphere over the ſurface of the excavation, which preſſure is as the baſes of the excavation, and theſe as the ſquares of the diameters; whereas the weights of ſimilar ſolids are as the cubes of theſe diameters; and, therefore, this preſſure being leſs, in proportion, in larger bodies than in ſmaller, the charges ought rather to be leſſened in large mines than in the ſmall. But this reaſoning ſeems to be contradicted by experiments.

In order to know the quantity of powder neceſſary for blowing up a mine in a particular ſoil, ſeveral mines are to be made in it, having their lines of leaſt reſiſtance equal, but loaded with different quantities of powder, till one is found to have the deſired effect. When this is found, the diameter of its baſe muſt be meaſured with the greateſt accuracy, and likewiſe the line of leaſt reſiſtance; and when theſe lines are determined, the parameter P of the parabola is found by the equation $KD = \sqrt{AD^2 + CD^2}$; and, having the parameter given, the quantity of earth or ſolid is found by the ſolid $P \times CD \times KD$, or by the rectangle $P \times KD$, as the lines of leaſt reſiſtance are different or the ſame. This ſolid, and the charge of the mine, will ſerve to find the effect of any other mine made in the ſame ſoil when the charge is given; or to determine the charge, ſo that the diameter of the baſe ſhall be of any given length, by means of the equation $P \times ED = AD^2$. The ſame being performed in all the different ſoils, which generally occur in making mines, will ſerve to make mines of any depth, or placed in any ſoil.

The miners divide the different ſoils into five ſpecies.

1. 2. 3. 4. 5. 6. } into {
1. looſe earth or ſand.
2. common middling light ſoil.
3. loam or ſtrong ſoil.
4. potters' clay, or ſtiff ſoil.
5. clay mixed with ſtones.
6. all kind of maſonry.

It has been found, that a cubic foot of the firſt weighs 95lb; of the ſecond, 124lb.; of the third, 126lb.; of the fourth, 135lb.; and 160lb. of the fifth. But as to maſonry, it cannot be determined to any degree of exactneſs, as depending on the different kinds of ſtones or bricks of which they are made.

It is pretended, that there are nine pounds of powder required to raiſe a cubic toiſe of the firſt kind; 11 of the ſecond; 13 of the third; 15 of the fourth; 18 of the fifth; and 20 or 25 to raiſe a cubic toiſe of maſonry above ground; and 35 or 40 for raiſing the ſame quantity under ground.

Theſe are the French weights and meaſures, which being reduced into Engliſh, give 8lb. of powder for the firſt kind of ſoil; 9.8 for the ſecond; 11.6 for the third; 13.4 for the fourth; 16 for the fifth; 18 or 22.3 for the maſonry above ground; and 31 or 35 for raiſing the ſame quantity under ground.

In the ſecond volume of M. Vauban's Attack and Defence of Places, he ſays, that the following rules never fail.

A cubic toiſe of common earth requires 14 pounds of powder to be raiſed.

Stiff ſand or loam, which may be dug without being ſupported, requires 17 pounds *per* toiſe.

Mixed earth requires 18 pounds *per* toiſe.

Potters' clay or ſtiff ſoil, 19 pounds *per* toiſe.

Fat or ſtiff earth mixed with pebble ſtone, 22lb.

Wet ſand, which cannot be dug without being ſupported, 15lb.

Theſe rules of M. Vauban make, therefore, the charges greater than thoſe of later miners.

But this is a matter which muſt be decided by experiments; and when theſe are made with ſufficient exactneſs, it will be eaſy to find the proper charge of a mine, ſo as the diameter of its baſe be of any given length; or when that length is given, to determine the charge required. *E. gr.* Let it be required to find the diameter of a mine made in the ſecond ſort of ſoil; which being loaded with 100lb. of powder, ſay, if 11 pounds raiſe a cubic toiſe, or 216 cubic feet of earth, how much will raiſe 100lb.; the fourth term, which is 1964, will be $= a$; and $2a = 3928$; and ſuppoſing the line of leaſt reſiſtance C D to be 10 feet, then will $c = 10$; hence the equation $c + P = \sqrt{\frac{2a}{a} + cc}$,

will

will give $c + P = \sqrt{402.8} = 20$; or $P = 10$, and $EC = \frac{1}{4}P = 2.5 : ED = 12.5$; whence the equation $P \times ED = \overline{AD}^2$, gives $10 \times 12.5 = 12.5 = \overline{AD}$, or $AD = 11.2$ nearly.

But to ſhew how far this theory agrees with the experiments mentioned before, we may ſuppoſe the firſt to be true, and from thence proceed to find what the diameters of the baſes of the others will be. All the lines of leaſt reſiſtances of theſe mines were ten feet each, the diameter of the baſe of the firſt mine was found to be $22\frac{2}{3}$ feet; ſo that AD is $= 11.33$, or 11.4 $CD = 10$; theſe values being ſubſtituted in the equation $KD = \sqrt{\overline{CD}^2 + \overline{AD}^2}$, will give $KD = \sqrt{229.96} = 15.16$; and $2KC = P = 10.32$; hence theſe values being ſubſtituted in the rectangle $P \times KD$, becauſe the line of leaſt reſiſtance is here always the ſame, gives $10.32 \times 15.16 = 156.5$, for the ſolid, which muſt be remembered, becauſe it is the ſtandard number whereby the other ſolids are determined.

Now if 120lb. gives 156.5, how much gives the charge 160lb. of the ſecond for its ſolid, the fourth term gives $208\frac{2}{3} = a$, and $2a = 417\frac{1}{3}$; this value, as well as that of $c = 10$, being ſubſtituted in $P + c = \sqrt{2a + cc}$, gives $P + c = \sqrt{517.4} = 22.7$; hence $P = 12.7$, $EC = \frac{1}{4}P = 3.2$, and $ED = 13.2$. Now theſe values being ſubſtituted in $P \times ED = \overline{AD}^2$, give $\overline{AD}^2 = 167.64$, and $AD = 13$ nearly; and as AB has been found by meaſurement to be about 26, it ſhews that this computation anſwers very nearly the experiment.

If as the charge 120 of the firſt is to the charge 200 of the third, ſo is the ſolid 156.5 of the firſt to the ſolid of the third; we ſhall have $a = 260.84$, or $2a = 521.68$; and as $c = 10$, the equation $P + c = \sqrt{2a + cc}$ gives $P + c = \sqrt{621.68} = 24.93$ nearly; hence $P = 14.93$, $\frac{1}{4}P = EC = 3.73$, and $ED = 13.73$; theſe values being ſubſtituted in $P \times ED = \overline{AD}^2$, give $AD = 14.32$, and $AB = 28.64$; which anſwers nearly the experiment; it was found that $AB = 29$ nearly.

If we proceed thus with regard to the 4th, 5th, 6th, and 7th experiments, we ſhall find the diameters of the baſe to be as follows; that of the 4th, 31.2; that of the 5th, 33.2; the 6th, 35.3; and that of the 7th, 37.4; which anſwers pretty near the experiments.

In this method of conſtructing mines, any opening may be made, whatever be the line of reſiſtance; and by making this line ſmall, and loading the mine with more powder, the inconvenience of a large excavation, which affords lodgment to the beſiegers, is avoided: beſides, the ſhafts and galleries are ſooner made, and ſeveral mines may be placed under one another, by which the ſame ſpot of ground may be blown up ſeveral times.

If it were required to make a mine in the ſame ſort of ſoil as that in which the ſeven experiments mentioned before were made, ſo that the line of the leaſt reſiſtance ſhall be equal to the radius of the baſe, and each of ten feet, and to find the quantity of powder neceſſary for its charge. Becauſe $AD = CD = 10$, the equation $KD = \sqrt{\overline{AD}^2 + \overline{CD}^2}$, will give $KD = \sqrt{200} = 14.14$; hence $P = 8.28$; theſe values being ſubſtituted in $P \times KD$, will give 117, nearly, for the ſolid; then if we ſay, as the ſolid 156.5, of the firſt experiment, is to the ſolid 117, ſo is the charge 120 to the charge required, it will be 90lb. nearly. But if it was required to find the quantity of powder neceſſary to raiſe a cubic fathom, or 216 cubic feet of this ſoil; then becauſe $CD = 10$ has been neglected in the ſolid 156.5, of the firſt experiment, as likewiſe the ratio r, therefore the quantity muſt be multiplied by $r \times 10$; or becauſe $r = 1.57$ by 15.7, which will give 2457; then if we ſay, as 2457 requires 120lb. of powder, how much will 216 require; and the fourth term, which is 10.5lb., will be the number ſought. From whence it appears, that the ſoil, in which theſe experiments were made, was a light ſort of ſoil, ſomewhat lighter than that which is taken by the miners for the ſecond ſort.

M. De Valliere ſuppoſes, in his table, inſerted below, that a mine, whoſe line of leaſt reſiſtance and radius of the baſe are each ten feet, requires $93\frac{3}{4}$lb. for its charge. Now, if it be required to find what kind of ſoil theſe mines are made in, by ſubſtituting the number for CD, AD, in the equation $KD = \sqrt{\overline{AD}^2 + \overline{CD}^2}$, we ſhall have $KD = \sqrt{200} = 14.4$, and $P = 8.28$; now theſe values being ſubſtituted in $rP \times CD \times KD$, we ſhall have $15.7 \times 8.28 \times 14.14 = 1838$; then if we ſay, as 1838 is to $93\frac{3}{4}$, ſo is 216 to 11. This fourth term will expreſs the number of pounds of powder required to raiſe a cubic fathom of the ſame ſort of ſoil, which therefore is the ſecond ſort.

The preceding computations have been made of French weights and meaſures, to ſhew how nearly the foregoing theory agrees with the experiments made at La Fere. It remains now to apply it to our own weights and meaſures; becauſe eight pounds of powder will raiſe a cubic fathom of earth of the firſt ſort; if we ſay a cubic fathom, or 216 cubic feet, is to eight pounds, as 1838 cubic feet is to 68.074 pounds, this fourth term will be the charge of a mine, whoſe line of reſiſtance is 10 feet as well as the radius of the baſe: in the ſame manner are found the charges of the ſame mine in the reſt of the ſoils. But the ſhorteſt way of computing tables is to ſubtract the logarithm of 216 from that of 1838, which gives 9298917; now if to this logarithm we add thoſe of 8, 9.8, 11.6, 13.4, 16; the weight of the powder required to raiſe a cubic fathom of the different ſoils, found before; we ſhall have 1° 83298, 2° 92112, 3° 99435, 4° 05699, 5° 14301 for the logarithms of the charges of a mine whoſe line of leaſt reſiſtance is 10 feet, and the diameter of the baſe 20.

Valliere's TABLE for the Charges of Mines.

By

By this conftruction the radii of the bafes being always equal to the lines of leaft refiftances, the folids are fimilar, and therefore are to one another as the cubes of their axes; that is, as the cubes of the lines of leaft refiftances. So that taking any one of the charges to be true, the others will be found by faying, as the cube of the axis whofe charge is given is to its charge, fo is the cube of the axis of any other mine to its charge.

For example, let the charge $93\frac{3}{4}$ of the mine, whofe line of leaft refiftance is 10 feet, be given; and it be required to find the charge of any other mine whofe line of leaft refiftance is given, fuppofe 15: then fay, as the cube 1000 of 10 is to the cube 3375 of 15, fo is the charge $93\frac{3}{4}$ to the charge required, which is 316.4, or 316 pounds 6 ounces, which is 2 ounces more than in the table. In the fame manner is found the charge of a mine whofe line of leaft refiftance is 20; or becaufe 20 is double of 10, the cube of 20 will be octuple the cube of 10; and therefore $8 \times 93\frac{3}{4}$, or 750 pounds, will be the charge of that mine.

A Table of the Charges of Mines according to Muller's Theory.

Diam.	Charge.	Diam.	Charge.	Diam.	Charge.
Feet.	Pounds.	Feet.	Pounds.	Feet.	Pounds.
22	150	42	639	62	1518
24	181	44	711	64	1621
26	217	46	773	66	1741
28	255	48	857	68	1842
30	297	50	946	70	1980
32	344	52	1020	72	2098
34	394	54	1115	74	2243
36	452	56	1205	76	2372
38	502	58	1299	78	2501
40	560	60	1406	80	2648

In this table the line of leaft refiftance is fuppofed to be always 10 feet, and the charges producing the openings at the fides of them from 22 feet to 80. It is fuppofed that the charge $93\frac{3}{4}$ of a mine, whofe line of leaft refiftance and radius of the bafe are each 10 feet, is given, and from thence all the reft are computed by means of thefe equations, $KD = \sqrt{AD^2 + CD^2}$, and $P \times KD = a$; and by comparing the diameters of the bafes found, by means of thefe equations, to be rather lefs than thofe found by experiments, it is prefumed that the diameters marked in this table will not be found lefs, but rather greater in practice.

In order to find the fize of the boxes, generally made cubical, in which the powder is lodged: as a cubic foot of common powder weighs about 55 pounds, if we fay as 55 is to unity, fo is any other quantity to its cube; *i. e.* if the given quantity of powder be divided by 55, the quotient will be the cube required, and its cube root will be the length of the fide of the box. The box muft always be made a fourth bigger than it fhould be, on account of the ftraw and fand-bags put in it, for keeping the powder free from wet; fo that if the quantity of powder be 360 pounds, the fourth part of it, or 90, muft be added, and the fum 450 divided by 55, whofe quotient is 8.1818, and the fquare root of this, or 2.86 feet, or 34 inches, will be the fize required. If the chamber happens to be placed on a rock, or any other hard fubftance, the force or action of the powder downwards, meeting with great refiftance, will be employed in raifing the earth upwards; and confequently the effect of the mine will be much greater than that produced by the fame quantity of powder, placed on a fofter fubftance. On which account, if a platform of ftrong planks were made under the chambers, there would be a lefs quantity of powder required for the charge of the mine. When the mine is properly loaded, the gallery is ftopped up with ftones, earth, and dung, well rammed, five or fix feet farther from the chamber than the length of the line of leaft refiftance. And for preventing the mine from burfting through the gallery, and to make it have its effect upwards, the gallery is made with one or two turnings, at right angles to each other, and ftrongly fecured with buttreffes and planks, and the intervals rammed with ftones and earth.

Many writers have eftimated the operation of mines on the falfe fuppofition, that their entonnoir, or excavation, is the fruftum of a cone; and therefore, in order to eftimate the weight of the matter to be blown up, they have only to compute the folidity of fuch a fruftum in cubic fathoms, and to multiply the number of fathoms by the number of pounds of powder neceffary for raifing the matter it contains; and if this cone contains matters of different weights, to take a mean betweeen them all; always having a regard to their degree of cohefion. As to the difpofition of mines, there is one general rule, which is, that the fide towards which one would determine the effect, be the weakeft; but this varies according to occafions and circumftances.

Mines, *Different Sorts of.* A mine which has only one chamber is called a fingle mine, as A, *fig.* 13. If it has two chambers, it is called double, as *fig.* 14, and if it has three, triple, as *fig.* 15, &c. the names being taken from the number of chambers. If a fingle mine is made under the rampart, to make breach, the entrance O, *fig.* 13, muft not be oppofite to the place where the chamber is defigned to be, but on one fide or other; and the gallery with two turnings, that it may be ftopped with greater fecurity, and that the diftance of the entrance O to the chamber A may be greater than the length of the line of leaft refiftance: otherwife the mine would have its effect that way. It muft alfo be obferved, that the chamber is placed in the middle of a counterfcarp, by which means it will make a greater breach than if it were placed in the earth behind the wall. When a double mine is made under the rampart for making breach, the entrance O, *fig.* 14, is made, as nearly as can be gueffed, in the middle, between two counter-forts; the gallery being carried quite through the wall in a direct line, turns afterwards to the right and left, in the form of a T; from whence it is alfo called a T mine; and the chambers are alfo placed in the next counter-forts, but exactly at equal diftances from the direct gallery: this double mine will make a much larger breach than the fingle one, and it is for that reafon preferred to any other.

But when a triple mine is to be made under the rampart, the opening O, *fig.* 15, is to be made directly oppofite to the counter-fort, if poffible, and carried directly through the wall, and turned to the right and left in the fame manner as the former; and the chambers A, B, at both ends, are placed in the two adjacent counter-forts. As to the gallery of the third, C, it is carried round the middle counter-fort, and the chamber placed under its extremity; this laft is generally

generally charged with fifty pounds of powder more than either of the others; but great care must be taken to carry the auger of this last chamber in zig-zags, so as to be equal in length to that of the chamber B, otherwise the fire would not reach them all three at the same time, and thereby the chamber C not take fire, which sometimes happens, and then the effect does not answer the expectation.

There are seldom or ever more made than a triple under the ramparts in sieges; but when a work is to be demolished, they make then as many as will demolish a whole face at once; which is done by giving the fire to all at the same time; that is, all the saucissons are brought into one, and so contrived, as that their parts from the chambers to the common junction may be exactly equal. Muller's System of Artillery, &c. vol. vi. part iii. p. 206, &c.

Mine, *Chamber of a.* See Chamber and Mine.

Mine, *Counter.* See Counter-*mine* and Mine.

Mine, *Gallery of a.* See Gallery and Mine.

Mine, *Knight of the*, is a military honour, anciently conferred on persons who had distinguished themselves in engagements in mines.

Mine-*Ships*, are ships filled with gunpowder, inclosed in strong vaults of brick or stone, to be fired in the midst of an enemy's fleet. See Fire-*ship*.

Mine is also a French measure. See Measure.

Mine-*Dial* is a box and needle, with a brass ring divided into 360 degrees, with several dials graduated thereon; generally thus made for the use of miners.

MINEHEAD, in *Geography*, a township of America, in Essex county, Vermont, on Connecticut river; it is watered by Nulhegan river, and has only 27 inhabitants.

Minehead, a cape of Ireland, in the county of Waterford, between Ardmore-head and Helwick-head, from the latter of which it is about four miles distant.

Minehead, a sea-port town and borough, situated on the southern shore of the Bristol channel, in the hundred of Carthampton and county of Somerset, England. The town was first incorporated by queen Elizabeth, who endowed it with many valuable privileges. In the reigns of Charles II. and queen Anne, so great was the trade from this port to Ireland, that upwards of forty vessels were constantly engaged in it. Several were likewise employed in the West India, Virginia, and Straits trade; and not less than 4000 barrels of herrings were annually shipped here for the Mediterranean. The chief articles of import, besides colonial produce, were wool, linen, and cattle, and the exports consisted mostly of coals and grain. All this trade is now entirely lost; the herrings have deserted the coast, and there are at present only five or six vessels belonging to the port. In the time of its prosperity the government of this borough was vested in a portreeve, but since its decline it has been committed to two constables, who are chosen annually at the court leet of the lord of the manor. The arms of the town are a ship under sail and a wool-pack, emblematical of its pristine trade.

Minehead is divided into three parts; the Upper Town, consisting of several irregular streets, meanly built, and standing on the eastern slope of a vast hill, called Greenalaigh or Minehead point; the Lower Town, situated half a mile from the beach to the south-east; and the Quay Town, placed under the brow of a lofty eminence close to the shore. The church, which is a large handsome structure, stands in the Upper Town, and is distinguished by a very elegant alabaster statue of queen Anne, on a pedestal four feet high. It was the gift of sir Jacob Banks, as appears from an inscription upon it, bearing the date 1719. At the entrance of the quay, in Quay Town, stands the Custom-house, which still continues furnished with a regular establishment of officers. A market continues to be held here every Wednesday; and there is a small manufacture of woollen cloths, which constitutes the chief support of the inhabitants. Fronting the market place is an alms-house, built and endowed by Robert Quirk, in 1630. Two members are sent from this borough to parliament, who are elected by the parishioners of Dunster and Minehead, being housekeepers and not receiving alms. The constables are the returning officers.

The country around Minehead is pleasing and beautiful, presenting to the view a series of lofty hills interspersed with rich and luxuriant vallies. The climate is so mild that vegetation is a month earlier here than in most parts of England. This circumstance has of late years induced many persons to resort hither during the bathing season, to the great benefit of the town. A peculiar species of limpet, found on the rocks here at low water, afford a very curious liquor used in marking linen, which, when first applied, exhibits a variety of changes in its colour, and ultimately, after washing, assumes a bright crimson hue, which no subsequent efforts will alter or eradicate. About six miles to the south of the town is the lofty mountain of Dunkerry, which rises 1770 feet above the level of the sea, and is 12 miles in circumference at the base. From the collections of stones bearing the marks of fire, which appear on different parts of it, it is conjectured to have been used as a beacon to alarm the country in the event of invasion. Collinson's History and Antiquities of Somersetshire, vol. ii. 4to. 1791.

MINELLI, Andrea, in *Biography*, a Venetian opera poet, and author of many dramas that were much applauded; such as "Orfeo," 1702; "Finezze d'Amore, et la forza vinta dall' Onore," 1703; "La Rodoguna," at Milan the same year; and "Il trofeo dell' innocenza," at Venice, 1704.

MINELLIUS, John, was born at Rotterdam about the year 1625, and passed his life as a teacher of the learned languages. He died in 1683. He published notes upon Terence, Sallust, Virgil, Horace, Florus, Valerius Maximus, and Ovid's Tristia, which have not only been very useful to students, but have been freely transcribed by more modern editors and commentators.

MINEO, in *Geography*, a town of Sicily, in the valley of Noto, near a lake of the same name; 24 miles S. of Catania.

MINERA, in *Medicine*, the seat, or rather matter of a disease.

The term is applied by some authors to those parts of the body wherein there are collections and coacervations of humours made; which, hardening, form obstructions, and produce diseases.

In this sense we say, the *minera morbi*, &c.

MINERALS, or Fossils, are those inorganical natural bodies of which the solid mass of the earth is composed. Their more remarkable properties and characters will be enumerated under the article Oryctognosy.

Mineral, *Æthiops.* See Æthiops, and Mercury.

Mineral, *Turbith.* See Turbith, and Mercury.

Mineral *Oil.* See Oil.

Minerale *Bezoardicum.* See Bezoardicum.

Mineral, *Crystal.* See Crystal *Mineral.*

Mineral *Kermes.* See Kermes *Mineral.*

Mineral *Waters*, are those which, at their springing forth from under-ground, are found impregnated with some mineral matter; as salt, sulphur, vitriol, &c. See Water.

Such are hot baths, spaws, purging, &c. springs.

Mineral *Waters, Earth of.* See Earth.

Mineral

Mineral *Juices*. See Juices.

Mineral *Courts*, *Curiæ minerales*, in *Law*, courts for regulating the concerns of lead mines; as *stannary courts* are for tin.

MINERALOGY, the science which makes us acquainted with all the various relations under which minerals present themselves to us. This comprehensive branch of knowledge is by the illustrious Werner divided into five distinct doctrines, viz. 1. *Oryctognosy*, or that part of mineralogy which, with the assistance of well ascertained characters and fixed denominations, teaches us to determine fossil substances, and to arrange them according to their natural affinities. 2. *Geognosy*, which has for its object the structure, relative position, and formation of those substances of which the crust of the earth is composed. 3. *Mineralogical Geography*, which exhibits, in geographical order, the species of rocks that occur in different countries, together with the various species of minerals contained in them, and the circumstances under which they occur. 4. *Mineralogical Chemistry*, which makes us acquainted with the various chemical properties of minerals, and with the quality and quantity of their component parts. 5. *Economical Mineralogy*, in which mineral substances are considered merely with a view to the use to which they are applicable, which also determines their arrangement.

It is only within the last quarter of the elapsed century that the knowledge of minerals has made rapid strides towards perfection; not long before that period it could scarcely be said to have assumed the appearance of a science; and the ancients appear to have been totally unacquainted with any thing in the shape of scientific mineralogy.

The ὀρυκτα and μεταλλευτα of Aristotle can scarcely be considered as bearing testimony to this philosopher's knowledge of minerals, and are indeed only mentioned by him because he fancied the origin of the former might be derived from earth, and that of the latter from water. The few mineral substances treated on by Theophrastus, Pliny, Dioscorides, and Galen, intermixed with productions of art, are merely such as were employed for the common purposes of economy, and the study of these authors is far more important to the philologist and antiquary than to the mineralogist. On reading the sixth book of Dioscorides, we become indeed acquainted with part of the medical knowledge of the ancients, but it teaches us very little that might be deemed any way interesting in a mineralogical point of view. Pliny, where he treats on gems and metals, expatiates on the luxury prevalent among the Romans, and when speaking of marble, basalt, &c. enters upon the history of their productions of art, without at all adverting to the degree of knowledge they possessed of unorganized nature. Indeed, *scientific* knowledge of this kind was not among the acquirements of the ancients; and whatever may have the appearance of it in the writings of the authors above-mentioned, is so destitute of order and precision, that it is surprising how Wallerius, who well knew what is requisite for a mineralogical system, could mention Theophrastus, Pliny, Dioscorides, and Galen, as the first systematical writers in mineralogy. The knowledge of some mineral substances must, of course, be coeval with the earliest ages of the world; but to trace mineralogy, as a science, to Egypt, or to ancient Greece and Rome, is almost as absurd as to dignify Tubal Cain with the title of the first of chemists.

When the general lethargy of the sciences commenced, little regard was paid even to the scanty knowledge handed down in the works of the ancients; and it was not till the introduction of the chemistry, or rather alchemy, of the Arabians into Europe, that a small share of attention was again bestowed on the study of unorganized bodies. Avicenna laid the foundation of the distribution of minerals, into stones, metals, sulphureous fossils, and salts; a division which was generally adopted by the chemists of those times, but not by the other naturalists; the former, to judge from a passage in Agricola (De Nat. Fossilium, l. i. p. xvii), not being held in great esteem by the scholiasts. "Avicenna," says Agricola, "non *scienter*, sed *more chimistarum*, sulphureo duas species subjecit: sulphur et arsenicum." Hence it is that Albertus Magnus, this superstitious transcriber of the ancients, followed quite a different distribution; for among other changes which he adopted, was that of throwing the salia and sulphurea into one class, under the name of *Media*.

Such were the first attempts at introducing some order among the unorganized bodies. The chemists on one side proposed the component parts, which, however, far from being demonstrated, were only hypothetically assumed by them: the scholiasts, on the other hand, were equally intent upon investigating and recommending the characters derived from the external form of minerals, their supposed medicinal properties and miraculous virtues. This twofold view of the subject characterizes the writings of almost all succeeding mineralogical authors, down to a period not far remote from the present; we find them either implicitly adopting the ideas of the chemists, or announcing themselves as mere empirical collectors of curiosities. Agricola, the first systematic mineralogical writer, may, indeed, be considered as an exception to this rule. He directed his thoughts to the uniting the views of these two classes of writers, although he certainly inclined more to those of the second.

Agricola was the first who paid attention to external characters, which were determined by him with tolerable precision, and employed for the distinction of the mineral substances then known. All fossils (corpora subterranea) are divided by him into simple, or such as consist of homogeneous particles; and into compounded, or such as are formed of heterogeneous parts, taken in a mineralogical acceptation of the terms. The minerals belonging to the former of these divisions are found in four different forms, which are, 1. Terra. 2. Succus concretus. 3. Lapis. 4. Metallum. *Terra* he defines as "corpus fossile quod potest manu subigi, cum fuerit aspersum humore, aut ex quo, cum fuerit madefactum, fit lutum." These earths he divides partly according to some external characters, partly after their localities, in cases where their names are derived from the countries or places in which they are found. "*Succus concretus* est corpus fossile siccum et subdurum, quod aquis aspersum aut non mollitur, sed liquescit, aut, si mollitur, multum vel pinguitudine differt a terra, vel materia ex qua constat." The fossils of this class Agricola divided into macra and pinguia; the former consist of a juice partly mixed with earth (sal nitrum), partly with metal (chrysocolla, ærugo, ferrugo, cæruleum), partly mixed both with earth and metal (atramentum sutorium, alumen, &c.): to the latter he refers sulphur, bitumen, sandarach, and auripigmentum. The ambiguity of this definition, and the impropriety of placing in one and the same class substances so very distinct from each other, require no comment. The stones are the third class of Agricola's system. "Lapis est corpus fossile siccum et durum, quod vel aqua longinquo tempore vix mollit, ignis vehemens redigit in pulverem; vel non mollit aqua, sed maximo ignis liquescit calore." The stones are subdivided into lapis, gemma, marmor, and saxum. His definition of metals, being his fourth class, is, "corpus fossile natura vel liquidum vel durum quidem, sed quod ignis liquescit calore." He enumerates ten metals. The last class of Agricola's system comprehends mixed and compound fossils. 1. Mixtures of stones and juices (succi). 2. Of earth and metal. 3. Of stone and metal. 4. Of juice, stone, and metal. To the second and third division he refers the various ores. What has been said may convey an idea of Agricola's systematic knowledge in mineralogy. Considered as a first essay, his system is indeed very valuable, and more logical precision in its execution can scarcely be expected from its author; but, on the other hand, it cannot be denied that he was often strangely led astray by his deficiency in chemical knowledge, nor did he even suspect that the preservation of unity is at all required in the construction of a system.

Most of the systematic mineralogical writers who succeeded Agricola were chemists, or rather alchemists; but even these adopted his system, although it was more or less altered by some of them. Thus, Cardanus retained the "succi concreti," but he followed the chemists in separating the salts from the bitumens.

Kentmann, who published in 1569 his book "De omni rerum fossilium genere," was a nomenclator who adopted Agricola's system almost without making any alteration. The earths and the succi concreti are, however, subdivided in a different manner, and a treatise on petrifactions is added, entitled "Alcyonia, conchæ et alia, quæ ex salso liquore maris et ex ejus spuma, cum tenuissimis sordibus permista concrescunt."

The celebrated botanist, Cæsalpinus, was the first who properly separated the salts from the inflammable fossils. The divisions of his system are, 1. Mineralia humore solubilia, to which he refers the earths and salts. 2. Oleo solubilia, which contains the sulphureous substances with orpiment. 3. Illiquabilia, comprehending the rocks, and all other stones, as also corals, animal calculi, &c. 4. Liquabilia, or metals.

Aldrovandus, that voluminous writer, compiled his system from Agricola, Cardanus, and Cæsalpinus. With him the petrifactions begin to be considered as objects of curiosity.

Besides the many authors of that period, who busied themselves by arranging the minerals of the ancients according to Agricola's system, which they now and then altered conformably to the supposed discoveries of the day, there were some who, although not systematic writers themselves, had considerable influence on the systems of succeeding periods. Among these was the famous Jesuit, Athanasius Kircher, who (in his Mundus subterraneus, Amsterd. 1678) surpassed all his precursors in the amassing of wonderful curiosities and *lusus naturæ;* although Jonston had not been remiss in affixing much importance to the strange forms representing celestial and sublunary bodies, presented to the world in his "Notitia regni mineralis," which appeared at Leipzig in 1661.

Of greater importance were the advantages which the science of mineralogy derived from the investigations of Beccher. This mineralogist (in his "Physica subterranea," first published in 1667,) considered water and earth as the remote, and vitreous, inflammable, and mineral earths (sal, sulphur, mercurius), as the proximate constituent parts of all minerals, which he accordingly arranged under three classes; the first comprehending such stones in which the vitreous earth constitutes the principal ingredient; the second and third class containing the substances in which the two remaining earths predominate. Though the principles which thus formed the base of his system were derived from gratuitous assumption, yet they served to prove the possibility of a chemical arrangement of the genera, and of applying the differences observable in the constituent parts of the earths and stones as fit characters for distinguishing them.

The stones Beccher divides into those that either calcine or vitrify in the fire; those that preserve their solidity, or become friable when ignited; and those that, when ignited and immersed in water, either remain solid or crumble to pieces. In his work, we for the first time find antimony, zinc, and bismuth, (though, indeed, also pyrites,) introduced as imperfect or semi-metals. The perfect metals, of which he has six in number (for mercury he considers as a *decompositum*), are classed after the following characters: two of them (gold and silver) melt in a red heat; two (copper and iron) are red-hot before they melt; and two (tin and lead) melt before they can be heated to redness.

The next in succession are the *decomposita*, or such minerals as are composed of several earths and stones, earths and metals, &c., or of several species belonging to the same class, such as mixtures of metals; and they are divided into terrea, lapidea, metallica, and aquea.

Bromelius (who published a book intitled "Catalogus rerum curiosarum," Gothenburg, 1698,) began to refer to the same class sulphur and the bituminous substances, which he called sulphurea and pinguia: he retained Beccher's division of metallic substances into perfect and imperfect metals.

Nor should the Swedish mineralogist Hiärne be left unnoticed here, who introduced several changes into the then prevailing system of mineralogy: thus, for instance, he was the first who separated the common from arsenical pyrites, which before him had constantly been united by authors. Like Bromelius he places sulphur and the bituminous substances in the same class; an arrangement which has been retained by all succeeding systematic writers in mineralogy: and though the term "succus concretus" continued to be employed by some of them, it was always used as a synonym of salt.

Towards the close of the 17th century Woodward published his catalogue of minerals. His knowledge of mineralogy was superior to that of any other English author of his time.

Of the mineralogists of the beginning of the 18th century, the most celebrated were Beyer, Bütner, and Scheuchzer. These authors, who were less superstitious and more to be depended upon than Aldrovandus and Kircher, principally presented the world with their observations on petrifactions. The two latter, however, were not quite free from prejudice; they introduced an excess of biblical teleology into the mineralogical science, and most of their observations were made with a view to the universal deluge. But it is not to be denied that all three contributed largely towards directing the attention of mineralogists to the structure of mountain rocks. All the mineralogical writers that had preceded them were chemists, practical miners, or at best mere oryctognosians: but about this period naturalists began to examine rocks with other than merely metallurgical views; mineralogy was found susceptible of being treated in a scientific manner, and it began to go hand in hand with the other branches of physical knowledge. Even Scheuchzer and Beyer, and some other authors of those times, by not confining themselves to the mere collecting of petrifactions, but also considering them as vestiges of important revolutions, had opened a new field of investigation to the thinking naturalist.

Magnus von Bromell, a Swede and pupil of Hiärne and Boerhaave, published a system of mineralogy, (Inledning til kundscab om Mineralier, &c. Stockh. 1730,) in which he not only availed himself of all the improvements made by his masters, but also proposed a new chemical division of stony substances into such as are refractory (apyri), or calcinable, or or vitrefcible, in the fire; to which were added the figured ftones (figurati.)

After Von Bromell, Linnæus appeared, and it is chiefly from this period that the origin of fyftematic mineralogy may be dated, when our fcience, together with the other branches of natural hiftory, acquired a degree of popularity which it had never before enjoyed. It has been queftioned whether Linnæus himfelf contributed to the advancement of the fcience; and fome writers have even denied him any knowledge in this department of natural hiftory. But the fact is that in his earlier years Linnæus devoted a confiderable fhare of time to the ftudy of mineralogy, and whatever his merits in framing his mineralogical fyftem may be, certain it is that it befpeaks the fame acutenefs and the fame original mode of thinking, which we fo much admire in the other works of this illuftrious naturalift. His mineralogical arrangement cannot, indeed, be compared with the mafterly fyftems of zoology and botany, and it even appears that he added it chiefly for the fake of completing his grand work of a general fyftem of nature. It has been juftly urged againft the applicability of his fyftem, that it is founded on an erroneous principle, *viz.* on the fuppofition that the cryftalline form of mineral fubftances is due to different falts, and that they are to be claffed accordingly; but even this erroneous notion ferved to direct the attention of the ftudent to the important characters derived from the diverfity of cryftallization, of which fubfequent mineralogifts availed themfelves with fignal fuccefs, for the diftinction and claffification of mineral fubftances. (See CRYSTALLIZATION.) If, moreover, we confider the advantages which neceffarily accrued to mineralogy by thofe general principles that were introduced into natural hiftory by Linnæus, the precifion of his terminology, his philofophical views of claffification, &c., all of which were equally applicable to our fcience, it can no longer be a matter of doubt that the labours of the great Swedifh naturalift have, at leaft indirectly, been of effential fervice to the advancement of this important branch of natural knowledge.

The chemical part of mineralogy began, about this period, to be cultivated with great fuccefs. The difcoveries of Henkel and Pott, who (if we except Hiärne, and perhaps Beccher) may be looked upon as the firft mineralogical chemifts, had clearly demonftrated the important advantages which mineralogy may derive from chemiftry. The external characters were almoft entirely rejected by Henkel as vague and unfatisfactory. In his "Idea Generalis de Lapidum Origine," the inflammable mineral fubftances (to which, however, he refers alfo vegetable gum and phofphorus) conftitute a feparate clafs; the clafs of falts contains acids, alkalies, and neutral falts, and the alkaline are kept diftinct from the earthy, and the latter from the metallic neutral falts; the earths he divides in the fame manner as Beccher, and he fubdivides them after the degree of heat required for their fufion; the clafs of ftones comprifes the calcareæ, filiceæ, calcareo-filiceæ or limofæ; a claffification which he propofes with great modefty, although it may indeed be confidered as a great ftep in mineralogical chemiftry. Henkel's "Kies-Hiftorie" (Hiftory of Pyrites), confidering the period in which it was written, difplays an uncommon degree of accuracy, and contains, as well as others of his works, valuable contributions towards the natural hiftory of various metallic fubftances, and their ores.

More accurate chemical knowledge marks the works of the celebrated Pott, who, on account of the valuable difcoveries illuftrative of mineralogy, may juftly be called the Klaproth of the period in which he flourifhed. No mineralogift before him had fo clearly demonftrated that it is the degree of hardnefs alone which diftinguifhes earths from ftones, and that this property, infinitely variable in various fubftances, cannot furnifh a principal diftinctive character for their claffification. Profound chemical knowledge and unintermitted application enabled him to fubject the fimple earths to a clofer examination, to determine their character with greater precifion, and alfo to augment their number. His claffification of the earths, which, with fome alterations, juftly became a ftandard for his fucceffors, is the following:—1. *Alcaline earth*, which may be burnt into quick-lime, and is foluble with effervefcence in the acids. 2. *Siliceous earth*, little alterable by calcination, and infoluble in acids: this he confidered as the principal caufe of hardnefs of the ftones in which it predominates. In his "Lithogeognofie," Pott called this latter "vitrefcible" earth; but finding afterwards that the property which gave rife to it is common to all the earths, he difcontinued the name. 3. *Argillaceous earth*, which, on account of its vifcidity and ductility, is fufceptible of being turned on the lathe, becomes hard in the fire, and is infoluble in the acids. 4. *Gypfeous earth*, which by burning is converted into gypfum, which refifts the acids, and is difficultly vitrifiable. The fpecies of earthy foffils were diftributed among thefe claffes, according as one or the other of the above earths formed the predominant conftituent part in them. Had this great chemift lived to extend to the metals the fame ftrict examination to which he fubjected the earths and ftones, mineralogy would undoubtedly, in his time, have arrived at that perfection which afterwards refulted from the laborious experiments of fucceeding chemical mineralogifts.

Nearly about the fame time Wallerius publifhed his fyftem of mineralogy (Mineral-rike indelt och befkrifvit, Stockholm 1747), in which, as the difcoveries of Pott were not then known to him, he adopts the claffification of the older mineralogifts, feparating earths from ftones, the former of which he divided into pulverulent earths (terræ macræ), argillaceous earths (terræ pingues), mixed earths (terræ minerales f. compofitæ), and fand (arenæ); the latter (with Bromell the younger) into lime-ftones (calcarei), vitrifiable ftones (vitrefcentes), refractory ftones (apyri), and rocks (faxa). The fubftances of the third clafs of his fyftem are called mineræ, comprehending faline ores (falia), inflammable fubftances (fulfura), and metals. The fourth clafs contains the concretions (concreta), which are fubdivided into ftalactical fubftances (pori), petrifactions (petrificata), figured ftones (figurata), and calculi.

This work of Wallerius was a welcome prefent to the mineralogical world. The genera before its appearance were extremely vague, and the external characters pointed out in the defcriptions were infufficient for the determination of a given foffil fubftance; it was indeed required to be previoufly acquainted with minerals in order to underftand the fyftematic works, and the knowledge of foffils was propagated more by tradition than by fcientific inftruction. One of the chief objects of oryctognofy, the determining a given foffil from defcription alone, even without any previous practical knowledge of mineral fubftances, was in a great meafure attained by this new work of Wallerius; the utility of which was greatly enhanced by the addition of a correct and critical fynonymy of preceding mineralogifts. But however great the advantages which accrued to the fcience by the labours of this excellent mineralogift, his fyftem was ftill, in many parts, effentially defective: thus, for inftance, the characters of the firft, fecond, and fourth claffes were derived from the external form, thofe of the third, on the other hand, from the mode of occurrence of the fubftances which it contains; the orders are chemically determined in the three firft

claffes,

classes, while those of the fourth class are derived from the form, and even the origin of the minerals referred to it. Nothing can be more vague than the definition he gives of concretions, which to him are "mineral substances composed of a fossil and common matter, formed in the usual manner, but hardened, and, as it were, cemented, either by fire or water, and therefore different from other minerals in their origin, figure, and the localities in which they occur."

Woltersdorf, a pupil of Pott, proposed to frame a system, embracing the whole mineral kingdom, in the manner of his master's system of lapideous substances; but his chemical knowledge appears to have been inadequate to the task which he undertook: his system, therefore, not being sufficiently supported by experiments, shared the fate of all attempts at natural arrangement not founded on actual observation, and proved abortive.

Pott's discoveries had paved the way to a more judicious and proper mode of framing classes and orders in mineralogy. In the same manner as botanists, in former times, separated trees from plants, mineralogists, equally misled by an apparently important external character, had kept the stones distinct from the earths; it was principally Pott who shewed the impropriety of this separation, and also that both earths and stones are divisible into several genera, according to the greater or less proportion they contain of the several chemically simple earths. The idea now presented itself, that perhaps in future the genera might be successfully determined after the number of earths which enter the composition of each, and that this principle of classification might be made subservient to the preservation of unity of the system. The salts were already arranged, also in the mineralogical systems, according to their more obvious chemical differences. To the class of metallic substances all such minerals were referred as chiefly contained metals, and the mineralized ores were no longer separated from the native metals. On the other hand, the writers on petrifactions, Bourguet, d'Argenville, &c. still followed closely the footsteps of Scheuchzer. Lusus naturæ, fossil productions imitative of organic structure, still occupied a conspicuous place in their arrangements, from which no systematic writer had yet dared to exclude them. To do this was reserved for Cronstedt.

With Cronstedt begins the second principal era of the science of mineralogy, if the first is to be dated from Agricola. In his work (Forsög til Mineralogie, &c. Stockh. 1758,) he sets out with giving some highly interesting and important observations on the gradual effects of fire and water on minerals, and on the slow but unintermitted changes they experience by physical and chemical agents in the bowels of the earth.

The minerals are divided by Cronstedt into earths, bitumens, salts, and metals. The earths are subdivided according to the difference in their mixture, as far as it was then known, into the following nine orders:—1. Calcareous stones; to which order also gypsum is referred. 2. Siliceous substances. 3. Granitic substances (garnet, basalt, shorl.) 4. Argillaceous substances. 5. Micaceous substances (mica, talc.) 6. Fluoric substances (fluor spar.) 7. Asbestine substances. 8. Zeolite, to which he refers also the lapis lazuli. 9. Manganesian substances (manganese, wolfram.) The salts are classed according to the acids or alkalies. The class of inflammables, which till then had been but little elucidated, has hardly undergone any alterations. He has, however, added the plumbago or graphite to it. The class of metals comprehends as many genera as simple metals were known in the author's time. For the first time we find here the then newly discovered platina, and also nickel, one of Cronstedt's own discoveries.

One of the principal and most striking advantages of this system, is the strict unity observed in the principle of classification, which is throughout chemical; and the principles on which these classes and orders are established are, still pretty generally acknowledged as genuine by the systematic mineralogists of the present day. The garnets were not separated by Cronstedt, from supposing them to contain a peculiar earth; on the contrary, he himself considers them as a mere variety of iron-shot quartz, and the separation was suggested by some peculiarities of external and physical characters presented by the garnets and shorls, the component parts of which were not as yet known to him. This unacquaintance with the constituent parts, and their peculiar chemical properties, likewise induced him to separate mica, talc, asbest, fluor, zeolite, and azur stone, manganese and wolfram from the other earths: though he actually suspected that the two former of these substances contained argillaceous earth, and that manganese and wolfram were known metals. Soon after, a new acid was discovered in fluor spar, a new earth in talc and asbest, and new metals in manganese and wolfram. In some instances he has deviated from the unity of his classification, particularly in the class of inflammable substances, to which, probably, on account of its use, iron pyrites is referred, though it does not display those properties which are mentioned as characteristic of that class. As, on one hand, Cronstedt's system is enriched with many new species, so, on the the other hand, this mineralogist properly rejected a great number of substances, which occupied a conspicuous place in the writings of his predecessors; for instance, the lusus naturæ, figured stones, &c. He also shewed that petrifactions cannot claim a separate place in the system merely because they have retained part of their original form; as also that compound mountain rocks are not admissible into a system which comprehends mineralogically simple substances. Both these natural productions are treated on in an appendix.

No work on mineralogy ever created greater sensation than that of Cronstedt. A short time after its appearance, it was translated into almost all European languages, the system was studied in all civilized countries, and with some occasional, often unnecessary deviations, was adopted by all writers on mineralogy. Yet with all this, Cronstedt's system is not without its great defects: thus, for instance, it is a matter of great difficulty to become acquainted with a mineral substance by consulting the description he gives of it. Cronstedt improved the classification of minerals, but the task of giving the greatest possible perfection to description, so indispensably necessary for the diagnosis of fossils, was reserved for succeeding mineralogists. He even neglected those external characters which were known and adopted in his time; but these, it must be confessed, were, for the greatest part, unsettled and vague.

At the same time with Cronstedt's Mineralogy, or immediately after, Lehmann and Vogel published their Systems, which, however, did not contribute much to the advancement of the science.

Marggraf demonstrated the peculiar nature of magnesian earth, which became the foundation for a new order of earthy substances. His writings contain, moreover, many discoveries highly important to chemistry, but which it is not necessary to detail in this place.

Wallerius was the first by whom the principles on which systematic writers had hitherto arranged mineral substances, were subjected to a strict examination. He rejected all characters derived from the value, use, and geognostic situation, and established it as a rule, that the orders and genera should be founded on chemical characters alone, while the species

species should principally be determined by their external characters. These principles he employed in the new edition of his "Mineralogical System," published at Stockholm in 1772. The nomenclature of no mineralogical writer before him had been equally correct and precise. His external characters, combined with the chemical ones then known, enabled the student, at least in some measure, to discriminate minerals by means of these improved descriptions. The genera, too, were distinguished by him with greater precision, and augmented with many new ones. In these respects Wallerius holds a most distinguished place among mineralogical writers, and his work still deserves to be consulted by the student in oryctognosy. It cannot, however, be denied that his terminology is still much too vague, and his external characters far from being sufficiently complete; for, as Werner very justly remarks, description is one of the principal objects of oryctognosy, and it is better to see a mineral badly arranged and well described, than well arranged and badly described. But even in his arrangement Wallerius has fallen into errors, which later discoveries might have taught him to avoid. In separating earths from stones he is not even faithful to his own principles of classification; and the reasons he assigns for so doing are, indeed, very unsatisfactory. His retaining the faulty division into vitrescible and fixed stones, his referring to one and the same class the salts, the sulphureous and bituminous substances, together with the metals, were among the more important defects in his classification.

It was about this time that Engström, by pointing out a more convenient method of trying some of the chemical properties of minerals by subjecting them to the flame urged by the blowpipe, greatly contributed toward facilitating the diagnosis of minerals, especially that of metallic substances.

Werner now published his classical work on the external characters of minerals, (Von den äussern Kennzeichen der Fossilien, Leipzig 1774,) upon the appearance of which the vague terminology which had, till then, rendered description almost useless, gave way to a settled and determinate language, and the foundation was laid of a system which has deservedly procured its framer the title of the father of systematic mineralogy. In the work just mentioned, all characters are described with uncommon precision, which may appear pedantic to those who are ignorant of the salutary effects which this very circumstance has on the discrimination of minerals. In 1780, Werner published a German translation of Cronstedt's Mineralogy, accompanied with notes, in which he makes us acquainted with his ideas respecting a system of oryctognosy. This was followed, in 1791, by a descriptive Catalogue of the Mineral Collection of M. Pabst von Ohein, in which we have the first authentic sketch of his system. These two works, and some highly interesting memoirs in "The Bergmännishe Journal," and some other periodical publications, is all that has been published by this great and modest mineralogist. All the expositions of his system which we possess are by his pupils; they are of various merit, and some of them are but ill calculated to convey an adequate idea of its excellencies. The late Mr. Kirwan, in his "System of Mineralogy," (a work of peculiar merit, on account of the many original observations which it contains) was the first who made the Wernerian system known in England; and after him professor Jameson, a distinguished pupil of the Freiberg school, has published an elaborate work in three volumes, the two first of which contain the system of oryctognosy according to the method of Werner, the third giving a complete exposition of his system of geognosy.

The fundamental principle laid down by Werner, in the systematical arrangement of fossils, is their natural affinity, which he allows to be founded on the chemical mixture of their component parts. These may be distinguished into essential and accidental component parts; the former of which alone are considered in the classification of mineral substances. The essential component parts are subdivided into predominant and characteristic ones; and generally the characteristic happen to be, at the same time, the predominant constituents. By Humboldt the former are called the enveloping constituent parts. All mineral substances are distributed by Werner into four classes, which are founded on what is called the fundamental constituent parts, *viz.* the earthy, saline, inflammable, and metallic; each class being called after that fundamental constituent part which predominates in and characterizes it. Thus we have the earths, the salts, the inflammables, and the metals. These classes are subdivided into genera, which are derived from the variety in the component parts of the minerals comprehended in each class; there being as many distinct genera as there are predominating, or, at least, characteristic constituent parts discovered in their mixture. Werner has himself disregarded this rule in several instances, and we suppose has now even entirely discontinued the division into genera; at least, several of his pupils have, in their systematic works, introduced *families* as the only division between class and species; each family being a group of species that manifest close affinity to each other, such as the "Feldspar family," the "Zeolite family," &c. By this means the system is so far freed from the shackles of chemistry, and the contradictions are avoided, which so frequently strike the student of the Wernerian system. In the same manner perhaps, also, the species might in some measure be made independent of chemistry. The character of the species, according to the original idea of the founder of this system, was to be derived from the chemical mixture, and from the differences in the quantity and quality of the constituent parts. But in most cases, where no analyses existed of minerals, or no satisfactory ones, external characters were substituted the more readily, as it is an axiom with Werner that a difference in external characters is indicative of a corresponding difference in the component parts, whether it be in their quantity and quality, or in the particular state of their chemical combination. If, therefore, a mineral differs from another related substance in three or more external characters, it is now considered as a distinct species. This circumstance accounts for the considerable number of species in the Wernerian system, compared with those of Haüy's, whose characters employed for specification are confined within a far more narrow compass. We shall shew in another place, that the laws for framing species in mineralogy, whatever the characters may be on which they are founded, must always be arbitrary: but fortunately for the science, the different opinions entertained by different schools respecting the nature of the species, is a mere matter of speculation, exerting little or no influence either on the diagnosis or the arrangement of mineral substances: for, provided the natural connection between two mineral substances remain undisturbed, it is certainly of no great importance whether one of them be degraded into a mere variety of its neighbour, or raised to the rank of a distinct species. Werner enumerates three different kinds of affinity of minerals, *viz.* the chemical, depending on the similarity of their constituent parts; the oryctognostical, consisting in the approximating resem-

resemblances of their external characters; and the geognostic affinity, denoting similarity in occurrence, relative age, &c. The species is subdivided by Werner into *subspecies* and *variety:* by the former are meant fossils belonging to the same species with another, but differing from it in two or three particular external characters; the latter is produced by the difference in any single external character, such as colour, fracture, &c.

The following is a tabular view of the Wernerian oryctognostic system, according to the improvements it has experienced up to 1803; to which are subjoined the additions lately made by its founder.

Class I. EARTHY FOSSILS. A. *Diamond Genus:* 1. Diamond. B. *Zircon Genus:* 2. Zircon. 3. Hyacinth. 4. Cinnamon-stone. C. *Flint Genus: Chrysolite Family:* 5. Chrysoberyl. 6. Chrysolite. 7. Olivine. 8. Coccolite. 9. Augite. 10. Pistacite. 11. Vesuvian.—*Garnet Family:* 12. Leucite. 13. Melanite. 14. Garnet; noble, common. 15. Staurolite. 16. Pyrope.—*Ruby Family:* 17. Spinelle. 18. Sapphire. 19. Emery. 20. Corundum. 21. Diamond spar. 22. Ceylanite. 23. Topaz.—*Shorl Family:* 24. Euclase. 25. Emerald. 26. Beryl; noble, shorlous. 27. Shorl; common. Tourmaline. 28. Axinite.—*Quartz Family:* 29. Quartz amethyst; (common, thick fibrous). Rock crystal. Milk quartz. Common quartz. Prase. 30. Iron flint. 31. Hornstone; splintery, conchoidal, wood-stone. 32. Flint slate; common, Lydian-stone. 33. Flint. 34. Calcedony; common, carnelian. 35. Hyalite. 36. Opal; noble, common, semi-opal, wood-opal. 37. Menilite 38. Jasper; Egyptian (red, brown), striped, porcelain, common (conchoidal, earthy). 39. Heliotrope. 40. Chrysoprase. 41. Plasma. 42. Cat's-eye.—*Pitch-stone Family:* 43. Obsidian. 44. Pitch-stone. 45. Pearl-stone. 46. Pumice.—*Zeolite Family:* 47. Prehnite; fibrous, foliated. 48. Zeolite; mealy, fibrous, foliated, radiated. 49. Cubicite. 50. Cross-stone. 51. Lomonite. 52. Schmelzstein (Dipyre, H.) 53. Natrolite. 54. Lazulite. 55. Azure-stone.—*Feldspar Family:* 56. Andalusit. 57. Feldspar; adularia, Labrador, common, (fresh, disintegrated), compact, hollow spar. 58. Scapolite. 59. Arctizite. 60. Spodumene. 61. Ichthyophthalmite.—D. *Clay genus: Clay Family:* 62. Pure clay. 63. Porcelain earth. 64. Common clay; loam, pipe-clay, potters' clay, (earthy,) variegated, and slate-clay. 65. Clay-stone. 66. Adhesive slate. 67. Polishing slate. 68. Tripoli. 69. Float-stone. 70. Alum-stone.—*Clay-slate Family:* 71. Alum-slate; common, glossy. 72. Bituminous shale. 73. Drawing-slate. 74. Whet-slate. 75. Clay-slate:—*Mica Family:* 76. Lepidolite. 77. Mica. 78. Pinite. 79. Pot-stone. 80. Chlorite; chloritic earth, chlorite slate, common and foliated chlorite.—*Trap Family:* 81. Hornblende; common, Labrador, basaltic, hornblende slate. 82. Basalt. 83. Wacke. 84. Clink-stone. 85. Iron-clay. 86. Lava.—*Lithomarge Family:* 87. Green earth. 88. Lithomarge; friable, indurated. 89. Rock-soap. 90. Umbra. 91. Yellow earth.—E. *Talc Genus: Soap-stone Family:* 92. Native magnesia. 93. Bole. 94. Meerschaum. 95. Fullers'-earth. 96. Steatite. 97. Bildstein.—*Talc Family:* 98. Nephrite; common, axe-stone. 99. Serpentine; common, noble, (conchoidal, splintery). 100. Schillerstein. 101. Talc; earthy, common, indurated. 102. Asbest; rock-cork, amianth, common asbest, rock-wood.—*Actinote Family:* 103. Kyanite. 104. Strahlstein; asbestous, common, glassy. 105. Tremolite; asbestous, common, glassy. 106. Salite.—F. *Lime-stone Genus: Carbonats:* 107. Rock-milk. 108. Chalc. 109. Lime-stone; compact, (common, roe-stone), foliated, (granular, calc. spar), fibrous, (common, calc. sinter,) pea-stone. 110. Lime-tuff. 111. Foam earth. 112. Slate-spar. 113. Brown spar; foliated, fibrous. 114. Schaalstein. 115. Dolomite. 116. Rhomb spar. 117. Stink-stone. 118. Marl; marl-earth, indurated m. 119. Bituminous marl-slate. 120. Arragon.—*Phosphats:* 121. Appatite. 122. Asparagus-stone. 123. Phosphorite.—*Fluats:* 124. Fluor; compact, F. spar.—*Sulphats:* Gypsum; earthy, compact, foliated, fibrous. 126. Selenite. 127. Anhydrite. 128. Cube spar.—F. *Baryte Genus:* 129. Witherite. 130. Heavy spar; earthy, compact, granular, curved lamellar, straight lamellar, columnar spar, prismatic spar, Bolognese spar.—G. *Strontian Genus:* 131. Strontian. 132. Celestine; fibrous, foliated.—H. *Halite Genus:* 133. Boracite. 134. Cryolite.

Class II. FOSSIL SALTS.—*Carbonats:* 135. Natural soda.—*Nitrats:* Natural nitre.—*Muriats:* Natural rock-salt; rock-salt, (foliated, fibrous,) lake-salt. 138. Natural sal-ammoniac.—*Sulphats:* 139. Natural vitriol. 140. Hair-salt. 141. Rock-butter. 142. Natural Epsom-salt. 143. Natural Glauber-salt.

Class III. INFLAMMABLE FOSSILS.—*Sulphur Genus:* 144. Natural sulphur; common, volcanic.—*Bituminous Genus:* 145. Mineral oil. 146. Mineral pitch; elastic, earthy, flaggy. 147. Brown coal; bituminous wood, earth coal, alum earth, common brown coal, moor coal. 148. Black coal; pitch coal, columnar, slaty, foliated, coarse, cannel coal.—*Graphite Genus:* 149. Glance coal; conchoidal, slaty, scaly, compact. 151. Mineral charcoal.—*Resin Genus:* Amber; white, yellow. 153. Honey-stone.

Class IV. METALLIC FOSSILS.—*Platina Genus:* 154. Native platina.—*Gold Genus:* 155. Native gold; gold-yellow, brass-yellow, greyish-yellow.—*Mercury Genus:* 156. Native mercury. 157. Native amalgam; semi-fluid, solid. 158. Mercurial horn-ore. 159. Mercurial liver-ore; compact, slaty. 160. Cinnabar; dark, light-red.—*Silver Genus:* 161. Native silver; common, auriferous. 162. Antimonial silver. 163. Arsenical silver. 164. Corneous silver-ore. 165. Silver black. 166. Silver glance. 167. Brittle silver glance. 168. Red silver-ore; dark, light. 169. White silver-ore. 170. Black silver-ore.—*Copper Genus:* 171. Native copper. 172. Copper glance; compact, foliated. 173. Variegated copper-ore. 174. Copper pyrites. 175. White copper-ore. 176. Grey copper-ore. 177. Copper black. 178. Red copper-ore; compact, foliated, capillary. 179. Tile ore; earthy, indurated. 180. Copper azure; earthy, indurated. 181. Malachite; compact, fibrous. 182. Copper green. 183. Iron-shot copper green; earthy, slaggy. 184. Copper emerald. 185. Copper mica. 186. Lenticular ore. 187. Olive ore. 188. Copper muriat.—*Iron Genus:* 189. Native iron. 190. Iron pyrites; common, radiated, hepatic, capillary. 191. Magnetic pyrites. 192. Magnetic iron-stone; common, arenaceous. 193. Iron glance; common, (compact, foliated,) micaceous. 194. Red iron-stone; red iron-froth, ochrey and compact red iron-stone, red hematite. 195. Brown iron-stone; brown iron-froth, ochrey and compact iron-stone, brown hematite. 198. Clay iron-stone; reddle, columnar, lenticular, jaspery, common, reniform, and pisiform clay-stone. 199. Bog iron-ore; morass-ore, swamp-ore, meadow-ore. 200. Blue iron-earth. 201. Pitchy iron-ore. 202. Gadolinite. 203. Green iron-earth. 204. Cube-ore.—*Lead Genus:* 205. Galena; common, compact. 206. Blue lead-ore. 207. Brown lead-ore. 208. Black lead-ore. 209. White lead-ore. 210. Green lead-ore. 211. Red lead-ore. 212. Yellow lead-ore. 213. Lead-vitriol. 214. Lead-earth; coherent, friable.

friable.—*Tin Genus:* 215. Tin pyrites. 216. Tin-ſtone. 217. Wood-tin.—*Biſmuth Genus:* 218. Native biſmuth. 219. Biſmuth glance. 220. Biſmuth ochre.—*Zinc Genus:* 221. Blende; yellow, brown, black. 222. Calamine.—*Antimony Genus:* 223. Native antimony. 224. Grey antimony; compact, foliated, radiated, plumoſe. 225. Black antimony. 226. Red antimony. 227. White antimony. 228. Antimony ochre.—*Cobalt Genus:* 229. White cobalt ore. 230. Grey cobalt ore. 231. Cobalt glance. 232. Black cobalt ochre; earthy, indurated. 233. Brown cobalt ochre. 234. Yellow cobalt ochre. 235. Red cobalt ochre; cobalt cruſt, cobalt bloom.—*Nickel Genus:* 236. Copper nickel. 237. Nickel ochre.—*Mangancſe Genus:* 238. Grey mangancſe ore; radiated, foliated, compact, earthy. 239. Black mangancſe. 240. Red mangancſe.—*Molybdena Genus:* 241. Molybdena.—*Arſenic Genus:* 242. Native arſenic. 243. Arſenical pyrites; common, argentiferous. 244. Orpiment; yellow, red. 245. Arſenic bloom.—*Scheele Genus:* 246. Tungſten. 247. Wolfram.—*Menachine Genus:* 248. Menachan. 249. Octahedrite. 250. Rutile. 251. Nigrine. 252. Iſerine.—*Uran Genus:* 253 Pitch ore. 254. Uran mica. 255 Uran ochre.—*Sylvan Genus:* 256. Native ſylva. 257. Graphic ore. 258. Yellow ſylvan ore. 259. Black ſylvan ore.—*Chrome Genus:* 260. Acicular ore. 261. Chrome ochre.

Werner has ſince added ſeveral new ſpecies to this liſt, and from the place aſſigned to one or two of them in the arrangement, it follows that this latter muſt alſo have undergone ſome ſlight alterations. Thus zoiſite is placed between piſtacite and axinite, which in the above tabular view are placed at ſome diſtance from each other. Augite is divided into common, foliated, conchoidal, and granular; and, as next ſpecies to it, the coccolite is added. The Siberian green garnet forms a diſtinct ſpecies next to garnet, under the name of groſſular. To the ſame natural family, Werner has now alſo added the cinnamon ſtone, (which, after Lampadius' incorrect analyſis, had before been placed in the zircon genus,) and the allochroit of d'Andrada. Between plaſma and cat's eye, the fettſtein or elæolite of Klaproth is placed. The ſpecies pumice is divided into three ſubſpecies, common, glaſſy, and porphyritic p. The dichroïte of Cordier is added, as iolite, to the pitch-ſtone family. The blue feldſpar of Stiria now forms a ſpecies diſtinct from, but next to feldſpar, under the name of blau-ſpath. A variety of compact feldſpar (jade of Sauſſure) is called variolite. Porcelain earth now ſtands next to feldſpar, from which it originates. Alſo the meionite and ſommit are united with this family. Potters' clay is now ſub-divided into earthy (formerly called pipe-clay) and ſlaty. To the three ſubſpecies of ſtrahlſtein or actinote is added a fourth, the granular. Silver-black is divided into friable and indurated. What was called capillary iron pyrites, has, by Klaproth's analyſis, proved to be native nickel. The menachine genus has received two additional ſpecies in the brown and the yellow menachan, inſerted after iſerine.

Having given this general idea of Werner's ſyſtem, we cannot proceed to that of Haüy, without making honourable mention of the celebrated Romé de l'Iſle, whoſe indefatigable reſearches ſo eminently contributed to the progreſs of the ſcience of mineralogy in general, and whoſe "Cryſtallographie" (of which the firſt edition appeared in 1773) is deſervedly characterized as the reſult of labours immenſe in their extent, almoſt entirely novel in their object, and of the higheſt importance on account of their utility. His claſſification of minerals has nothing peculiar; but for the accuracy, completeneſs, and elegance of his deſcriptions, and particularly his ſcientific method of determining the cryſtalline forms, he ſtood unrivalled among the mineralogiſts of his time. For an account of the labours of this father of cryſtallography, the reader is referred to the article Crystals.

Several memoirs of Haüy, illuſtrative of his theory of the ſtructure of cryſtals, were followed, in 1801, by that celebrated profeſſor's great work, entitled "Traité de Minéralogie." In this important and truly claſſical production, the new theory (of which a detailed view is given under the article Crystallography) is alſo made ſubſervient to the claſſification of mineral ſubſtances. Haüy has defined the mineralogical ſpecies "an aſſemblage of bodies, the integrant molecules of which are ſimilar to each other, and have the ſame compoſition." According to his mode of viewing the ſubject, minerals have both a geometrical and a chemical limit; the former conſiſts in the invariable form of the molecule, the other in the compoſition of the ſame molecule. Haüy prefers making uſe of the geometrical limit for determining the ſpecies, not only becauſe minerals being in general more or leſs mixed with heterogeneous matter, it often happens that the chemical limit is but imperfectly repreſented by the reſults of the analyſis, whereas mechanical diviſion invariably furniſhes the ſame form of the molecule; but principally becauſe the geometrical limit is far more obvious and palpable, ſince to obtain it nothing is in many caſes required but the mechanical diviſion of the cryſtal. In caſes where the integrant molecule belongs excluſively to a determined combination of component principles, it alone is ſufficient to diſtinguiſh the ſpecies; but there are forms of molecules which are common to ſeveral diſtinct ſpecies; and theſe forms, as far as they are known, happen to poſſeſs the peculiar character of ſymmetry and regularity, conſtituting, as it were, limits with reſpect to other forms. As in this latter caſe the character derived from the integrant molecule is not ſufficient, Haüy adds to it another, chemical or phyſical, character for the diſcrimination of the ſpecies: thus, for inſtance, the property of diſſolving in water, ſuper-added to the cubic form determines muriate of ſoda, or common ſalt; but if the ſame form is united to the property of becoming electric by heat, we have borate of magneſia, or boracite. The type of the ſpecies, according to Haüy, being once determined, it is comparatively eaſy to arrange the varieties of cryſtallization belonging to the ſame ſubſtance, by aſcertaining, with the aſſiſtance of the theory of decrements, whether all their forms, even thoſe which no longer retain a trace of the primitive form, are in exact correſpondence with the latter. With regard to the varieties, ſuch as thoſe compoſed of fibrous, granular, or compact maſſes, of which the type, though it ſtill exiſts in them, can no longer be determined, their diſcrimination depends on the phyſical and chemical properties of the ſubſtance, ſuch as hardneſs, ſpecific gravity, electricity, &c. What regards the genera and upper diviſions, the diſtribution is made after the component parts or chemical properties common to all the ſubſtances contained in the ſame diviſion. The method adopted by Haüy, in his deſcription of the mineral ſpecies, is the following. At the head of the deſcription of each mineral is placed the eſſential character, founded on the moſt conſtant properties which diſtinguiſh its individuals; after which follow the phyſical, the geometrical (comprehending the cleavages and primitive form of the ſubſtance), and the chemical character; to which is added the diſtinctive character, in which the differences are pointed out which diſtinguiſh the ſubſtance in queſtion from others which might be eaſily miſtaken for it. Theſe general characters are followed by the enumeration of the varieties of form (divided into determinable and undeterminable), the varieties depending on light, ſuch as colour, tranſparency, &c.

The

The following outline of Haüy's diſtribution is principally taken from his "Tableau comparatif des Réſultats de la Cryſtallographie, et de l'Analyſe chimique," Paris, 1809. The names included in parentheſes are thoſe of the Wernerian ſchool.

Claſs I. *Acidiferous Subſtances.* *Order* I. Diſengaged acidiferous ſubſtances. 1. Sulphuric acid. 2. Boracic acid. *Order* II. Earthy acidiferous ſubſtances. A With ſimple baſe:—*Firſt Genus:* Chaux (lime), ſp. 1. 3. Chaux carbonatée, (compriſing all the Wernerian ſpecies of carbonates of lime, with the exception of the following ſpecies). 4. Arragonite. 5. Chaux phoſphatée (apatite). 6. Ch. fluatée (fluor). 7. Ch. ſulfatée (gypſum and ſelenite). 8. Ch. anhydro-ſulfatée (anhydrite). 9. Ch. nitratée. 10. Ch. arſeniatée (arſenic bloom; pharmacolite, Klapr.)—*Second Genus:* Baryte. 11. Baryte ſulfatée (barytes or heavy ſpar). 12. Baryte carbonatée (witherite).—*Third Genus:* Strontian. 13. S. ſulfatée (celeſtine). 14. S. carbonatée (ſtrontian). —*Fourth Genus:* Magneſie. 15. M. ſulfatée (natural Epſom or bitter ſalt). 16. M. boratée (boracite). 17. M. carbonatée (native magneſia or talc earth).—*Fifth Genus:* Lime and ſilica. 18. Chaux boratée ſiliceuſe (datholite).—*Sixth Genus:* Silica and alumine. 19. Silice fluatée alumineuſe (topaz and pycnite, or ſhorl beryl).

Order III. Acidiferous alkaline ſubſtances.—*Firſt Genus:* Potaſſe. 20. P. nitratée (natural nitre).—*Second Genus:* Soude. 21. S. ſulfatée (natural Glauber ſalt). 22. S. muriatée (rock-ſalt). 23. S. boratée (tinkal, K.) 24. S. carbonatée (natural ſoda or natron).—*Third Genus:* Ammoniaque. 25. A. ſulfatée (maſcagnin, K.). 26. A. muriatée (natural ſal ammoniac).

Order IV. Acidiferous alkaline-earthy ſubſtances. 27. Alumine ſulfatée alcaline (alum)—*Appendix.* 28. Alumine fluatée alcaline (kryolite). 29. Glauberite.

Claſs II. Earthy ſubſtances. (No ſubdiviſion into orders) 30. Quarz (the whole of Werner's quarz family compriſing fourteen of his ſpecies). 31. Zircon (zircon and hyacinth). 32. Corindon (corundum, ſapphire, diamond-ſpar, emery). 33. Cymophane (chryſoberyl). 34. Spinelle (ſpinel, ceylanit). 35. Emeraude (emerald, beryl). 36. Euclaſe. 37. Grenat (garnet, melanite). 38. Amphigène (leucite). 39. Idocraſe (Veſuvian). 40. Meïonite. 41. Feld-ſpath (feldſpar). 42. Apophyllite (fiſh-eye ſtone, or ichthyophthalmite). 43. Triphane (ſpodumen). 44. Axinite. 45. Tourmaline (ſhorl). 46. Amphibole (all the ſub-ſpecies of hornblende, except Labrador hornbl., actinote, augite and tremolite partly). 47. Pyroxène (augite, ſahlite). 48. Yenite. 49. Staurotide (ſtaurolite). 50. Epidote (piſtazite, zoiſit). 51. Hyperſthène (Labrador hornblende). 52. Wernerite (arktizit). 53. Paranthine (ſcapolite). 54. Diallage (var. of actinote, ſchillerſtein). 55. Gadolinite. 56. Lazulite (azur-ſtone). 57. Meſotype (fibrous and mealy zeolite, nadeſtein). 58. Stilbite (radiated and foliated zeolite). 59. Laumonite (lomonit). 60. Prehnite. 61. Chabaſie (ſchabaſit). 62. Analcime (kubizit). 63. Nepheline (nephelin; ſommit, K.) 64. Harmotome (croſs-ſtone). 65. Peridot (chryſolite, olivine). 66. Mica (glimmer or mica). 67. Pinite. 68. Diſthène (cyanite). 69. Dipyre (ſchmelz-ſtein; dipyr, K.) 70. Aſbeſte. 71. Talc. 72. Marle (hollow ſpar; chiaſtolite, K.)

To this claſs are appended the following ſubſtances, the characters of which are not ſufficiently well underſtood to aſſign them their reſpective places in the ſyſtem.

Allochroite (ſplintery garnet, K.) Alumine pure (pure clay). Amianthoïde. Antophyllit, Schum. and Wern. Aplome. Bergmannit, Schum. Diaſpore. Feldſpath apyre, H. (andaluſit). Feld-ſpath bleu (var. of compact feldſpar). Fibrolite, Bourn. Gabbronite, Schum. Jade (common nephrite, axe-ſtone). Jolithe, W. and K. Kaneel or cinnamon ſtone, W. Lazulit, W. Latialite (Haüyne). Lepidolite, W. Melilite, Fleuriau. Natrolite, W. Pſeudo-ſommit, Fleur de B. Spath en tables (ſchaalſtein). Spinellane. Spinelle zincifère? (automalite). Spinthère, H. Talc? granuleux (earthy talc), and T. glaphique (bildſtein; agalmatolite, Kl.)

Claſs III. Combuſtible not metallic ſubſtances.—*Ord.* I. Simple. 73. Soufre (ſulphur). 74. Diamant (diamond). 75. Anthracite (kohlenblende, glanz-kohle).—*Ord.* II. Compounds. 76. Graphite. 77. Bitume (mineral oil; mineral pitch). 78. Houille (black coal). 79. Jayet (pitch coal). 80. Succin (amber). 81. Mellite (honey-ſtone).

Claſs IV. Metallic ſubſtances.—*Ord.* I. Not immediately oxidable, except by a very high degree of heat, and immediately reducible.—*Firſt Genus:* Platina. 82. P. natif ferrifère (native platina).—*Second Genus:* Or. 83. O. natif. (native gold).—*Third Genus:* Argent. 84. A. natif (native ſilver). 85. A. antimonial (antimonial ſilver); as appendix to it, A. antimonial ferro-arſénifère (arſenical ſilver). 86. A. ſulfuré (vitreous ſilver-ore). 87. A. antimonié ſulfuré (red-ſilver-ore); and as appendix to it, A. antimonié ſulfuré noir (brittle vitreous ſilver). 88. A. carbonaté. 89. A. muriaté (horn-ore or horn-ſilver).—*Ord.* II. Immediately oxidable and reducible: Mercure. 90. M. natif (native mercury). 91. M. argental (native amalgam). 92. M. ſulfuré (cinnabar); and as appendix, Mercure ſulfuré bituminifère (mercurial liver-ore). 93. Mercure muriaté (mercurial horn-ore).—*Ord.* III. Oxidable, but not immediately reducible: *a*, ſenſibly ductile.—*Firſt Genus:* Plomb. 94. P. natif volcanique. 95. P. ſulfuré (galena); by way of appendix, P. ſulf. antimonifère, and P. ſulf. antimonifère et argentifère (weiſſgultig-erz). 96. P. oxydé rouge. 97. P. arſeniaté (flokken-erz, K.) 98. P. chromaté (red lead-ore). 99. P. carbonaté (white lead-ore); and, as appendix, P. carb. noir (black lead-ore, lead earth), and P. carb. cuprifère. 100. P. phoſphaté (brown and green lead-ore). 101. P. molybdaté (yellow lead-ore). 102. P. ſulfaté (natural lead vitriol).—*Second Genus:* Nickel. 103. N. natif (capillary iron pyrites). 104. N. arſenical (copper nickel). 105. N. oxydé (nickel ochre).—*Third Genus:* Cuivre. 106. C. natif (native copper) 107. C. pyriteux (copper pyrites); and, as appendix, C. pyr. hépatique (variegated copper ore). 108. C. gris (grey copper ore). 109. C. ſulfuré (vitreous copper ore). 110. C. oxydulé (red copper ore and tile ore). 111. C. muriaté (ſaltz-kupfer). 112. C. carbonaté bleu (copper azur). 113. C. carb. vert (malachite; copper green). 114. C. arſeniaté (lenticular copper ore; olive ore); as appendix, C. arſen. ferrifère (cupreous arſeniate of iron, Bourn.) 115. C. dioptaſe (copper emerald). 116. C. phoſphaté. 117. C. ſulfaté (copper vitriol, K.)—*Fourth Genus:* Fer. 118. Fer natif (native iron). 119. F. oxydulé (magnetic iron-ſtone); and, by way of appendix, F. oxydulé granuliforme (iron-ſand). 120. F. oligiſte (ſpecular iron, iron mica, red iron froth, red hematite; compact red iron-ſtone, columnar clay iron-ſtone). 121. F. arſenical (common arſenical pyrites); and, as appendix, F. arſenical argentifère (weiſs-ertz, W. noble arſenical pyrites, K.) 122 F. ſulfuré (common pyrites); and, as appendix, F. ſulfuré épigène (leberkies, but not of Werner), and F. ſulfuré ferrifère (magnetical pyrites). 123. F. oxydé (brown hematite; reniform and lenticular clay iron-ſtone; green iron-earth); and, as appendix, F. oxydé réſinite (eiſenpech-erz, or pitchy iron-ore); alſo part of F. oxydé carbonaté (ſparry iron-ſtone). 124. F. phoſphaté (blue iron earth). 125. F. chromaté (eiſen-chrom, K.) 126. F. arſeniaté (cube ore). 127. F. ſulfaté

ſulfaté (native vitriol).—*Fifth Genus:* Etain. 128. E. oxydé (tin-ſtone); and, as appendix, E. oxydé concrétionné (Corniſh tin ore, or wood-tin). 129. E. ſulfuré (tin pyrites).—*Sixth Genus:* Zinc. 130. Z. oxydé (calamine). 131. Z. carbonaté. 132. Z. ſulfuré (blende). 133. Z. ſulfaté (zinc vitriol, K.)—*b*, not ductile.—*Seventh Genus:* Biſmuth. 134. B. natif (native biſmuth). 135. B. ſulfuré (biſmuth glance); and, as appendix, B. ſulf. plumbo-cuprifere (needle ore). 135 B. oxydé (biſmuth ochre).—*Eighth Genus:* Cobalt. 137. C arſenical (white and grey cobalt-ore). 138. C. gris (cobalt glance). 139. C. oxydé noir (black cobalt ochre). 140. C. arſeniaté (red cobalt ochre).—*Ninth Genus:* Arſenic 141. A. natif (native arſenic). 142. A. oxydé (arſenic bloom). 143. A. ſulfuré (yellow and red orpiment).—*Tenth Genus:* Manganèſe. 144. M. oxydé (grey and black manganeſe ore); and, as appendix, M. oxydé carbonaté (red manganeſe ore). 145. M. ſulfuré (manganeſe glance, K.) 146. M. phoſphaté ferrifère (phoſphor. mangan, K.)—*Eleventh Genus:* Antimony. 147. A. natif. (native antimony). 148. A. ſulfuré (grey antimony ore). 149. A. oxydé (white antimony ore; antimony ochre). 150. A. oxydé ſulfuré (red antimony ore).—*Twelfth Genus:* Uran. 151. U. oxydulé (pitch ore). 152. U. oxydé (uran mica; uran ochre).—*Thirteenth Genus:* Molybdena. 153. M. ſulfuré (molybdena).—*Fourteenth Genus:* Titane. 154. T. oxydé (rutil; menakan). 155. T. anataſe (octaedrit). 156. T. ſiliceo-calcaire (ſphen).—*Fifteenth Genus:* Scheelin. 157. S. ferruginé (wolfram). 158. S. calcaire (tungſten).—*Sixteenth Genus:* Tellure. 159. T. natif; auro-ferrifèré (native ſylvan), argentifère (graphic ore); auro-plombifère (nagyag ore).—*Seventeenth Genus:* Tantale. 160. T. oxydé ferro-manganéſifère (tantalit, K.) and yttrifère (yttro-tantalite, K.)—*Eighteenth Genus:* Cerium. 161. C. oxydé ſiliciſère (cererit, K.)

Two appendices contain, the one, all the compound rocks; the other, the volcanic productions. As neither of theſe claſſes of minerals form a prominent or diſtinctive feature in the ſyſtem, it is only neceſſary in this place to mention the ſubdiviſion of thoſe aſſemblages. The rocks are divided into aggregates of primary, ſecondary, and tertiary formation, and into thoſe compoſed of fragments or detritus cemented together ſubſequent to the formation of the ſubſtances to which they belonged. The volcanic productions are divided into ſix claſſes: 1. Lavas, (ſubdivided into lithoid, glaſſy, and ſcorified). 2. Thermantides, or ſubſtances preſenting only ſlight traces of volcanization. 3. Products of ſublimation, ſuch as ſulphur, &c. 4. Altered lavas. 5. Volcanic tuffas. 6. Subſtances formed in the interior of lavas, ſuch as meſotype, &c. Conf. Anon. über das Studium der Mineralogie. Haüy's Tabl. comparatif. Lucas' Tabl. des Eſpéces minerales.

MINERVA, La, in *Geography*, a town of Naples, in the province of Otranto; 20 miles E.S.E. of Matera.

Minerva, in *Mythology*, derived according to ſome *à minis*, from the threats of her ſtern countenance, otherwiſe called *Pallas*, is the goddeſs of wiſdom and the arts; and the only one of the offspring of Jupiter to whom pertain the prerogatives of the ſupreme rank of divinity. Minerva is repreſented, both by the painters and poets of antiquity, as a beauty of the ſeverer kind: the diſtinguiſhing character of her face is dignity and a certain ſternneſs, which has more of maſculine than feminine in it: and, therefore, more apt to ſtrike one with awe and terror, than to charm one, at firſt ſight. Her dreſs and attributes are adapted to the characters of her face; ſhe moſt uſually appeared with a helmet on her head, and a plume that nodded formidably in the air; in her right hand ſhe ſhook her ſpear, and in her other graſped her ſhield, with the head of the dying Meduſa upon it; the ſame figure appears alſo on her breaſt-plate called Egis, which was the ſkin of a goat, or, as others ſay, of a monſter ſo called, which vomited fire and committed dreadful havoc in Phrygia, Phœnicia, Egypt and Libya, and which was killed by Minerva, and hence ſhe wore its ſkin upon her buckler; and ſometimes the goddeſs herſelf is repreſented as having living ſerpents about her breaſts, and about her ſhoulders; ſhe is alſo accompanied with a cock, which is a fighting bird, and correſponding to her character as the inventreſs and preſident of war, and an owl, which ſees in the dark, and, therefore, is the image of wiſdom. It is probable that the Romans conſidered Jupiter, Juno, and Minerva, as one and the ſame divinity, under three different names: among which names, that of Jupiter might ſignify ſupreme goodneſs; that of Minerva, ſupreme wiſdom; and that of Juno, ſupreme power: thus the learned Dr. Cudworth obſerves, Intell. Syſt. b. 1. c. 4. p. 450, that the three Capitoline gods, Jupiter, Juno, and Minerva, may be underſtood to have been nothing elſe but ſeveral names and notions of one ſupreme deity, according to its ſeveral attributes and manifeſtations. Cicero mentions five goddeſſes of the name of Minerva, and Clemens Alexandrinus admits alſo the ſame number. Several cities were diſtinguiſhed by the worſhip which they paid to Minerva; among others Rhodes and Athens, but Sais in this reſpect rivalled all the cities in the world, for here this goddeſs had a magnificent temple, which Herodotus has particularly deſcribed. The ſame author alſo ſpeaks of temples conſecrated to this goddeſs in ſeveral cities of Greece; but the iſland Dio, or Naxos, though conſecrated to Bacchus, was more remarkable for the worſhip of Minerva, which appears by her repreſentation on three medals of that city. At Athens ſhe had a magnificent temple, called "Parthenos," the virgin, which Phidias adorned with a ſtatue of gold and ivory, reckoned his maſter-piece. The worſhip of Minerva was rendered ſtill more ſolemn by a feſtival, called "Atheneia," celebrated to her honour, and the pomp of which invited ſpectators from all Greece. This feſtival afterwards took the name of "Panathenaia," in which was a proceſſion, when the people carried about the "peplus" of Minerva, which was a white robe without ſleeves, wrought with gold, on which were repreſented the combats and great achievements of Minerva, Jupiter, and the Hermes.

Minerva is alſo ranked among the muſical deities, to whom the invention of the flute is aſcribed. See Flute.

MINERVALIA, among the Romans, called alſo *Quinquatria*, were feaſts celebrated in honour of Minerva. One of theſe feaſts commenced on the 3d of January, and another on March 19th, and laſted five days. The firſt day was ſpent in prayers to the goddeſs; the reſt in offering ſacrifice, ſeeing gladiators fight, acting tragedies upon mount Albanus, and reciting pieces of wit, wherein the conqueror had a prize given him. Scholars had then a vacation, and made a preſent to their maſters, which was called *Minerval*.

MINEUR, Fr., Minor, Lat., a muſical term applied to ſuch concords and intervals, as are rendered as flat or ſmall as poſſible, without being falſe and out of tune. Mineur is ſaid alſo of a key or mode in which the third above the key note is minor or flat. See Mode, Major, and Interval.

MINGALLA, in *Geography*, one of the ſmall weſtern iſlands of Scotland, the largeſt of thoſe called "Biſhop's iſlands," about three miles long and one broad. N. lat. 56° 48′. W. long. 7° 35′.

MINGAN Islands, a cluſter of iſlands near the ſouth coast of Labrador, in the gulf of St. Laurence, so called from the name of the principal of them. N. lat. 50° 15'. W. long. 64°.

MINGHIOL, signifying "Thousand Springs," a mountain in the northern part of Armenia, abounding with springs; from which the Euphrates originates.

MINGO, an Indian town on the W. bank of the Ohio river, 40 miles south-westerly of Pittsburg. In the creek, where it is situated, there are springs, that yield the "petrol," a bituminous liquid.

MINGOES, an Indian nation, inhabiting the vicinity of the southern branch of the Scioto river. The number of warriors is 40.

MINGOLZHEIM, a town of the duchy of Baden; 14 miles S.E. of Spire.

MINGOTTI, Regina, in *Biography*, a female opera singer and actress of great abilities and celebrity, was born in Carinthia, a German province, in the dominions of Austria, and though a native of a transalpine country, she became one of the most eminent vocal performers on the Italian opera stage during the last century. After seeing and hearing her frequently in England, where she arrived in the year 1754, we met with her, in 1772, at Munich, in Bavaria, and in conversation obtained from her the following sketch of her active professional life.

Her parents were Germans; her father, an officer in the Austrian service, being called to Naples upon duty, his wife travelled with him thither during her pregnancy, and was there brought to bed of this daughter; who, however, was carried to Gratz, in Silesia, before she was a year old; and her father dying while she was young, her uncle placed her in a convent of Ursulines, where she was educated, and where she received her first lessons of music.

She told us, that during her childhood, she remembers being so pleased with the music performed in the chapel of her convent, particularly with the Litany sung there one festival, that she went to the abbess, with tears in her eyes, and trembling, both with fear of anger, and of a refusal, to intreat her to teach her to sing, as *she* did in the chapel. The abbess put her off, with saying, that she was very busy that day, but would think of it. The next day she sent one of the elder nuns to ask her who bid her make that request, when the little Regina, as she was then called, replied, that nobody had bid her, but that it was merely her own love for music which inspired the thought. After this the abbess sent for her, and told her, that she had very little time to spare; but if she would promise to be diligent, she would teach her herself; adding, that she could only afford her half an hour a day; but with that, she should soon find what her genius and industry were likely to produce, and she should go on with, or discontinue her instructions accordingly.

Regina was in rapture with this compliance of the abbess, who began to instruct her the next day, *à table sec*, as she expressed it, without a harpsichord, or any other instrument. She applied to the harpsichord several years after, and still accompanied on it very well. But it was perhaps owing to her manner of learning to sing *without* an instrument, that she acquired the firmness in performance, for which she has always been remarkable.

In this manner she was taught the elements of music and *solfeggi*, with the principles of harmony, and was obliged to sing the treble, while the abbess sung the base. She shewed us a very small book, in which all her first lessons were written: the explanations were in the German language.

She remained in this convent till she had attained her 14th year, at which time, upon the death of her uncle, she went home to her mother. During the life of her uncle, she had been intended for the veil. When she quitted the convent, she appeared, in the eyes of her mother and sisters, to be one of the most useless and helpless of beings; they looked upon her as a fine lady, brought up in a boarding school, without knowing any thing of houshold concerns; and her mother neither knew what to do with her, or her fine voice, which both she and her sisters despised, not foreseeing that it would one day be productive of so much honour and profit to the possessor.

Not many years after she quitted the convent, signor Mingotti, an old Venetian, and manager of the opera at Dresden, was proposed as a husband for her. She detested him, but was at length worried into a compliance, which was the sooner extorted from her, perhaps, as she, like other young women, imagined that by losing, she should gain her liberty.

People talked very much of her fine voice and manner of singing. Porpora was at this time in the late king of Poland's service, at Dresden: he had heard her sing, and spoke of her at court as a young person of great expectations; which occasioned a proposal to her husband for her entering into the service of the elector: he had before marriage promised never to suffer her to sing on the stage; however, he came home one day, and asked her, if she should like to engage in the service of the court. She thought this was done in derision, and gave him a short and peevish answer; but he continuing to teize her on the subject, at length convinced her that he was in earnest, and had a commission to treat with her. She liked the thoughts of singing, and turning her voice to some account, and therefore gladly entered into articles for a small stipend, not above 3 or 400 crowns a-year.

When her voice had been heard at court, it was supposed to raise a jealousy in Faustina, who was then in that service, but upon the point of retiring; and consequently, in Hasse, her husband, particularly when he heard that Porpora, his old and constant rival, was to have 100 crowns a month for teaching her. He said it was Porpora's last stake; the only twig he had to catch at; *un clou pour s'accrocher*. However, her talents made such a noise at Dresden, that the fame of them reached Naples, to which place she was invited to sing at the great theatre. In her way thither from Dresden she passed through Vienna, where she visited unexpectedly Metastasio, in whose "Attilio Regolo" she had distinguished herself; of which visit he gives the following account to the princess di Belmonte.

"Signora Regina Mingotti, one of the principal ornaments of the vocal band at Dresden, being engaged at Naples in the same rank, has not escaped the epidemic desire of bringing with her a letter from me to your excellence. This request, however, would have been fruitless, had she not most wickedly and maliciously hit upon the following expedient, for vanquishing my well-known repugnance to give way to such applications. When she left the court of Dresden, what does she do but post away to Vienna; and without giving me the least previous notice of my danger, early one fine morning presents herself in my room, and in a military habit, preceded only by her fame, and accompanied by all the graces of youth, vivacity, talents, and what is still worse, entitled to the chief credit of the success of my "Attilio" in Dresden. Now tell me madam, with your usual candour, if ever you heard of so cunning a musical trick, it was like putting a knife to the throat of a poor Christian. I know not what Socrates, Cato, or Aristotle would have done in such a case; but this I know, that

that I could not help writing the letter, and even devoutly thanking heaven, that ſhe had the moderation to limit her pretenſions to a letter only."

This letter has no date, but it muſt have been written in 1751, when "Attilio" was firſt repreſented at Naples.

At this time ſhe knew but little Italian; however, ſhe now went ſeriouſly to work in ſtudying it.

The firſt character ſhe appeared in was Ariſtæa in the opera of the "Olimpiade," ſet by Galuppi. Montecelli performed the part of Megacles. On this occaſion her talents, as an actreſs, gained her as much applauſe as her ſinging: ſhe was bold and enterpriſing; and, ſeeing the character in a different light from what others had done before her, would, in ſpite of the advice of old actors, who durſt not deviate from cuſtom, play it in a way quite different from any one of her predeceſſors. It was in this original and courageous manner, that our Garrick firſt ſurpriſed and charmed an Engliſh audience, and, in defiance of contracted rules, which had been eſtabliſhed by ignorance, prejudice, and want of genius, ſtruck out a ſtyle of ſpeaking and acting, which the whole nation has ever ſince continued to approve, with acclamation, rather than applauſe.

After this ſucceſs at Naples, Signora Mingotti received letters from all parts of Europe, to offer her terms for engaging at different operas; but ſhe was not then at liberty to accept of any of them, being obliged to return to the court of Dreſden, in which ſervice ſhe was ſtill a penſioner; however, her ſalary was conſiderably augmented, and ſhe frequently expreſſed her gratitude to that court, and ſaid ſhe owed to it all her fame and fortune. Here ſhe repeated, with great applauſe, her part in the "Olimpiade;" every one agreed, that in point of voice, execution, and acting, her powers were very great; but many thought that ſhe was wholly unfit for any thing pathetic or tender.

Haſſe was now employed to ſet "Demofoonte;" and ſhe imagined that he kindly gave her an adagio, accompanied by the violins, Pizzicati, merely to expoſe and ſhew her defects. But ſuſpecting the ſnare, ſhe ſtudied hard to eſcape it; and in the ſong, "Se tutti i Mali Miei," which ſhe afterwards ſung in England with great applauſe, ſhe ſucceeded ſo well, as to ſilence even Fauſtina herſelf. Sir Ch. H. Williams was Engliſh miniſter here at this time, and being intimate with Haſſe and his wife, had joined their party, publicly declaring that Mingotti was utterly unable to ſing a ſlow and pathetic ſong; but when he had heard her, he made a public recantation, aſking her pardon for doubting of her abilities, and ever after remained her firm friend and adherent.

She went next to Spain, where ſhe ſung with Gizziello, in the operas under the direction of Farinelli; who, ſhe ſaid, was ſo rigid a diſciplinarian, that he would not allow her to ſing any where but in the opera at court, or even to practiſe in a room next the ſtreet. She was requeſted to ſing at private concerts by many of the firſt nobility and grandees of Spain, but could not obtain permiſſion from the director; who carried his prohibition ſo far, as to deny a pregnant lady, of great rank, the ſatisfaction of hearing her, though ſhe was unable to go to the theatre, and declared that ſhe longed for a ſong from Mingotti. The Spaniards have a religious reſpect for theſe involuntary and unruly affections in females thus circumſtanced, however they may be treated as problematic by M. Buffon and others. The huſband, therefore, of the lady, complained to the king of the cruelty of the opera director, who, he ſaid, would kill both his wife and child, if his majeſty did not interfere. The king lent a favourable ear to the complaint, and ordered Mingotti to receive the lady at her houſe, in which his majeſty was implicitly obeyed, the lady's deſire was ſatisfied, and the child prevented, perhaps, from being marked in ſome part of its body with a muſic paper, or from having an Italian ſong written with indelible characters on its face.

Mingotti remained two years in Spain, whence ſhe came to England, for the firſt time, in 1754. How much her performance was then admired many perſons now living can well remember, and tradition has told the reſt. She afterwards ſung in every great city of Italy: but always regarded Dreſden as her home during the life of Auguſtus, the late king of Poland. She was now ſettled at Munich, more it was thought from economy than attachment. She had no penſion from the court of Bavaria, as was reported; but with care and prudence, ſhe had juſt ſufficient from her ſavings to bring her ſafely through the year. She ſeemed to live very comfortably, to be well received at court, and to be eſteemed by all ſuch as were able to appreciate her underſtanding, and enjoy her converſation.

It gave us great pleaſure to hear her ſpeak concerning dramatic muſic, which ſhe did with more intelligence than any maeſtro di cappella with whom we ever converſed. Her knowledge and experience in ſinging, and powers of expreſſion in different ſtyles, were ſtill aſtoniſhing, and muſt have delighted all ſuch as could receive pleaſure from ſong unaccompanied with the blandiſhments of youth and beauty. She ſpoke three different languages, German, French, and Italian, ſo well, that it was difficult to ſay which was her own. Engliſh ſhe likewiſe ſpoke, and Spaniſh, well enough to converſe in them, and underſtood Latin; but in the three languages firſt mentioned ſhe was truly eloquent.

Her ſtyle of ſinging was always grand, dramatic, and ſuch as diſcovered her to be a perfect miſtreſs of her art; ſhe was a moſt judicious and complete actreſs, extending her intelligence to the poetry, decorations, and every part of the drama. Yet her greateſt admirers allowed that her voice and manner would have been more irreſiſtible, if nature had allowed her a little more female grace and ſoftneſs. Her performance of male parts, however, obviated every objection that her greateſt enemies could make to her perfection, either as a ſinger or actreſs.

The firſt time Mingotti came to England, ſhe remained here three years; during part of which time ſhe and Giardini were joint managers; by which their celebrity was more increaſed by their talents, than their fortune by the profits of the theatre.

MINGRAY, in *Geography*, a town of Spain, in Catalonia, near the mouth of the Tet; 15 miles E. of Gerona.

MINGRELIA, a country of Aſia, the ancient *Colchis*, (which ſee), is bounded on the N. by Circaſſia, on the E. and S.E. by Imeritia, on the S. by Guriel, and on the W. by the Black ſea and Abaſcia. This country is woody, intermixed with a ſmall proportion of arable land, which is ſo ſoft as ſcarcely to bear the plough. The climate as well as the ſoil is relaxed by moiſture; and it is ſaid that in many places the ground ſounds hollow, from which circumſtance originates an opinion, that the Euxine and Caſpian are connected by a ſubterraneous communication. Mingrelia is watered by the Phaſis, and a great number of other rivers. The chief food of the inhabitants is "gom," a grain reſembling millet; wheaten bread is uſed only by the prince and nobility. This country was originally rich in gold, and hence, it has been ſaid, the Argonauts fetched the golden fleece; but the mines of precious metals are now unwrought. Ancient Colchis, of which Mingrelia is a part, contained a great number of cities and towns, moſt of which have long ſince ſunk into oblivion. The preſent capital of this part of Turkey in Aſia, called Cotatis or

Cutais,

Cutais, comprehends hardly 200 houſes, though it is the reſidence of the prince. The air is rendered inſalubrious by frequent rains, and the inhabitants ſeldom protract their lives beyond 60 years. The vines of the country produce excellent wine, and the paſtures, which are excellent, feed many horſes. The men, as well as women, are generally well formed and handſome; but they are reckoned, in general, to be thieviſh, perfidious, cruel, drunken, and licentious in their amours. Infants, that have no means of ſupport, are often put to death, as well as ſick perſons, of whoſe recovery there is no reaſonable expectation. The people are generally employed in the chaſe, and they think themſelves peculiarly happy, if they poſſeſs a horſe, a good dog, and a well-trained falcon. The peaſants are ſlaves to the nobility; who have the power of life and death over their vaſſals in Mingrelia, as well as Imeritia, Guriel, and Georgia. Their religion is that of the Greek church. The principality is hereditary, and the prince or chief of Mingrelia and Guriel aſſumes the title of "Dadian," or the chief of juſtice; and the tribute exacted by the Turks is a quantity of linen cloth, manufactured in the country. The principal commerce is in ſlaves.

MINHO, Lat. MINIUS, which is ſaid to derive its name from "Minium," or vermilion, found in its neighbourhood, is a river of Spain, that riſes on the E. of the Sierra Mondonado, in the province of Galicia, receives the waters of the Cuytella and the Ouaria, paſſes to Lugo, receives the Chouro, and at San Martino de Coba the Sil, and then purſuing the boundary of Galicia, ſeparates it from Portugal, whence it proceeds and falls into the ocean near the port of Guardia; its courſe is about 52 leagues, firſt from N. to S., then to the S.W.

MINIACI, or CASALINO, a town of Sicily, in the valley of Demona; 10 miles S.W. of Randazzo.

MINIATO, ST., a town of Etruria, on the Arno, the ſee of a biſhop, containing four churches beſides the cathedral and nine convents; 20 miles W. of Florence. N. lat. 43° 44′. E. long. 10° 49′.

MINIATURE, in *Painting*, a word borrowed of the French, and derived, as ſome ſay, from the Latin *minimum*. It properly ſignifies the repreſentation of natural objects, by figures drawn and painted in ſmall proportions; but there is ſomething arbitrary in its preſent uſe, as it is almoſt entirely confined to portraits painted with water-colours on paper, vellum, or ivory; and is not applied to ſmall figures painted in oil, on wood, ſtone, or canvas. Thus, Gerard Dow's and Adam Elſheimer's very finely executed works, wherein ſometimes are figures not more than two or three inches high, and conſequently far ſmaller than miniature portraits are uſually painted, which ought therefore, according to the preceding etymology of the word, to be called miniatures, never are ſo, but are conſtantly ſpoken of as ſmall pictures. But we conceive that the term miniature is derived, agreeably to the ſtatement of other writers, from *minium*, vermilion, whence the perſons who put the red letters, and illuminations in ancient manuſcripts, were called *miniatores*.

In this branch of the art of painting, the ſame feeling of character, the ſame taſte and underſtanding of drawing and chiaro-ſcuro are requiſite, as in oil painting; but the uſe of its materials is more facile, and leſs likely to produce, in unſkilful hands, ſuch diſcordant and unpleaſant effects, though the proceſs is more tedious. It requires great ingenuity and patience in the artiſt, as it is wholly performed with the point of the pencil, either applied in the manner termed hatching, which conſiſts of fine ſtrokes croſſing or intermingling with each other; or that of ſtippling, or laying dots of various colours over the ſurface of the picture. One of theſe modes of proceeding is neceſſary to produce ſoftneſs, with fullneſs and richneſs in miniature; becauſe ivory and vellum, from the peculiarity of their textures and ſurfaces, do not admit of the ſyſtem called waſhing, or blending the colours together in a broad ſoft manner, like aqua-tint: and in works like theſe, whoſe beauties are not diſcernible but on a near inſpection, great neatneſs and perfection in the finiſhing are imperiouſly demanded.

The miniatures which are of the oldeſt date in England were chiefly wrought on vellum, though the cabinets of our nobility and gentry contain ſome few in oil colours on thin copper-plates: and this latter ſyſtem might well have been adopted generally, but for the difficulty of producing the eſſential beauties of miniature, *viz.* clearneſs and purity, with ſo groſs a vehicle as oil is, when compared with water; and alſo, that there is much danger, if the picture be worn, of ſome of the colours changing, and becoming dark: otherwiſe, and if merely hung up for ornament, a decided preference muſt be given them for their durability over thoſe painted in water colours.

The adoption of ivory for miniature painting, in preference to vellum, which, although limited in ſize, is now almoſt univerſal, is founded on three circumſtances, *viz.* its being ſo much leſs likely to be affected by damp, capable of receiving a ſmoother texture, and having a more agreeable hue of colour, which greatly blends with the freſher hue of the fleſh, and gives it warmth and harmony. It alſo poſſeſſes a degree of abſorption, which renders the colours leſs likely to fade. So great is the effect of damp upon vellum, or of the ſubſtances employed to ſmooth and prepare its ſurface for the artiſt, that there are few miniatures painted upon it, of recent date, even the colours of which are not in ſome meaſure impaired; and in many they are almoſt totally deſtroyed.

The colours beſt adapted for miniature painting are thoſe that have the leaſt body, and that work clear and clean in hue; ſuch as lakes, carmine, ultramarine, browns, yellows, and greens made of the juices of certain herbs and flowers. Moſt of the earthy colours, as the ochres, by no means are eaſily applied to this purpoſe: their opacity and body render them unfit agents, where all ſhould be light, ſplendid, and clear. The vehicle which beſt ſuits the purpoſe is water, in which either gum Arabic or gum tragacanth is diſſolved. The colours ſhould be firſt ground in pure water, and the gum-water added afterwards, in ſufficient quantity to give them tenacity, that they may not eaſily rub off the ſurface of the ivory or vellum; but if too much gum be uſed, there is great danger of the colours cracking and falling off.

In the proceſs of miniature painting, our modern artiſts cover the ivory with colours more than was uſually done by thoſe of an early period, who were accuſtomed to leave the naked ground or colour of that ſubſtance in a large proportion in the fleſhy parts, and contented themſelves with little more than drawing very delicately the features of their ſitters on it, and rounding the extremities with ſhadows. Though much more rotundity and richneſs of effect is gained by the preſent proceſs, when ſkilfully employed; yet in hands leſs ingenious, there is great danger of heavineſs, and loſs of character and ſimplicity, thoſe prime and ineſtimable qualities in all works of art, the want of which cannot be compenſated for by all the colour and delicacy of finiſh the utmoſt ſtretch of art, without them, is capable of producing. But, in fact, the capabilities of water colours are become far more known and underſtood of late, as well as the beſt modes of applying them. A new ſchool in that branch of art has ariſen in the courſe of the laſt ten or fifteen years; ſince when, effects have been produced by them, which leave all former experience of their power far behind, and of which nothing could have been expected. Of this more under the article Water-*Colours*.

The most successful artists in miniature in this country, till the present period, were Nicholas Hilliard and Isaac Oliver, in the time of Elizabeth; and P. Oliver and S. Cooper, in that of Charles I. The works of the latter are particularly striking, and worthy of observation, for the extraordinary breadth of manner, which he appears to have caught of Vandyke; many of whose pictures he copied in miniature, and which his own pictures resemble so much, that a magnifying glass only exhibits to greater effect the simplicity of the style in which they are wrought.

We now possess a great number of very ingenious artists in this branch of the profession: but to particularize any one, when so many stand on nearly the same level, would be invidious; and the public have ample opportunities of deciding on their respective merits.

For the method of preparing ivory for miniatures, see Ivory.

MINICULATOR, among the Romans, a servant who embellished any writing with minium.

MINIET, or Minieh, in *Geography*, a small but somewhat handsome town, compared with other places in the same country, in Upper Egypt, on the west banks of the Nile. Its streets, however, are narrow and dusty: the houses are built of unbaked bricks, cemented with mud; and many of its edifices are clumsy and irregular. The house occupied by the kiaschef or cachef, as well as those of some other persons, are built of stone, and their whiteness relieves the uniform reddish-grey of the rest. The bazars, or places where the merchants meet, are tolerably commodious; and the crowds which frequent them announce a numerous population, as well as some briskness of trade. Government has here established a toll for loaded vessels, which is easily collected, as the Nile is not wide at this place. Here are manufactured earthen vessels, called "bardacks," formed of clay in the neighbourhood, and serving to preserve the water cool. Columns of granite, broken and thrown down, and some still standing, besides heaps of rubbish, intimate that Miniet occupies the place of a more ancient city; which, according to some, was "Hermopolis," and, according to others, "Cynopolis," where the dog was worshipped. Mr. Bruce supposes Miniet to be the ancient "Philæ." It is about 50 leagues from Cairo, 22 miles S. of Abu Girgé, and 14 N. of Ashmuneim, or Achmounim.

Miniet *Rabiné*, a town of Egypt; 6 miles S. of Gizeh.

Miniet *Selamé*, a town of Egypt; 10 miles S. of Faoué.

Miniet *Semannud*, a town of Egypt; 8 miles S. of Mansora.

MINIM, in *Music*, from *minimus*, Lat., the least. In the first time-table that was framed, where the semibreve was the shortest note, and the first in a round form, the rest were square. But as the art of counterpoint was improved, and different parts in notes of different value were attempted, it was found necessary to divide the semibreve in two equal parts, , ; diminishing the length of a semibreve one half, by adding a tail to it. This invention has frequently been ascribed to Vitriaco; but it seems more properly to belong to Franco, as appears by a manuscript tract in the Bodleian library at Oxford. Franco flourished 200 years before Vitriaco. See Musica *Mensurabilis*, Time, Measure, and *Musical* Characters.

Minim, *Sextuple of the*. See Sextuple.

MINIMA Naturæ, or *Minima Naturalia*, among *Philosophers*, the primary particles of which bodies consist; the same with what are otherwise called *corpuscles*, and *atoms*.

Minima, in the *Higher Geometry*, the smallest quantities attainable in any given case. See Maxima.

Minima, *Per*. See Per *Minima*.

MINIME, in old French *Music*, was the same character for time as is now called *une blanche*. See Minim and Time-table.

MINIMENTS, or Muniments. See Muniments.

MINIMI *Digiti Extensor*. See Extensor.

Minimi *Digiti Pedis Abductor*. See Abductor.

MINIMS, Minimi, an order of religious, instituted about the year 1440, by S. Francis de Paulo, confirmed in 1473, by Sixtus IV., and by Julius II. in 1507. See Bons-*Hommes*.

These have improved on the humility of the Minors, by terming themselves *Minimi* or *Minims*, *q. d.* least, or smallest.

MINIMUS Gluteus. See Gluteus.

MINING, *History of*. To trace this subject up to its earliest stages, and to exhibit the various combinations of human ingenuity which it has in successive periods produced, though an inquiry which might afford matter for curious speculation, would be one which, if we were to take into the view the progress of mining in all the different countries where metals have been found, would extend the subject to a length hardly admissible in any work not wholly devoted to this object.

From the simplest operations, mankind have been gradually led, by following the pursuit of the metals, to efforts the most complex and astonishing. At first it may be assumed, not only from the probability of the thing, but from evidence which even this country affords, in the remains of ancient works of this kind, that metals were procured from detached fragments of the ores, such as had been separated by various causes from the upper parts of the veins in which they were originally deposited: and in this manner is gold yet procured, by washing the sands of certain rivers; and tin even now sought after, under beds of gravel, in the vallies of Cornwall and Devon.

The pursuit of scattered pieces of ore naturally would conduct the persons, who were thus employed, to the beds from which they had been detached; and in turning over the soil to procure the loose fragments, the backs of the veins would be laid open and discovered. This is a process which is even now daily going on in mining districts, only with a different object: for having found an accidental stone of ore, the miner does not now dig over the earth on the surface, for the sake of these casual deposits; but reasoning from their appearance that a vein is near at hand, goes at once to work in order to find it.

If we allow that this account of the origin of mining be true, it ought to follow that those metals were most anciently worked, whose ores are most attractive in their appearance, most easily reduced into a metallic state, or such as are most usually found near the surface of the earth. As far as the English mines afford us the means of judging, all this may be asserted to be true. The tin of Cornwall was undoubtedly the first metal sought after in Britain, and probably the first article of commerce with other nations; and the ores of tin, from their great weight, indicate their metallic contents, and yield them to the simplest treatment with fire, and are still found at inconsiderable depths. It may also be observed, that the traces of the most ancient tin works exhibit no symptoms of their having been pursued, but in situations where the soil, with which it was mixed, could be easily and expeditiously removed; or where it could

could be washed away by streams of water, conducted over it for the purpose, and which, by carrying off the lighter parts of the soil, laid bare the ores, which are kept from moving by their superior specific gravity.

This latter was an ingenious improvement upon the first ruder efforts, and is still the mode employed in many of the tin stream works; while there are numerous traces of these attempts accompanied with circumstances, which prove them of very considerable antiquity.

Lead is another metal, which not only is often found near the surface, but the ores exhibit to the eye the appearance of metal, and in general yield their contents to the heat of a moderate fire. This metal, therefore, was probably an object of pursuit in the early ages of mining.

Copper, on the other hand, is seldom found without penetrating the earth to considerable depths; and the proportion of metal in most of the ores is so small, that a certain progress in the arts of mining and smelting must be presumed to have been made, before it could have become an object of research. We believe this to have been the fact in most countries, as well as in this, where copper was certainly discovered by working mines in pursuit of tin or lead.

From the processes for finding and separating metallic ores from alluvial matter in which they were casually mixed, the next step was to procure them by digging out the veins themselves, and following them into the solid rocks in which they are formed. At first this could only have been done, where, by the elevation of the mountains, it was possible to work high enough for the waters to discharge themselves by conduits or adits from the works; and where the rock was not so hard but to yield to tools rudely formed, or perhaps to the agency of fire, which would, however, produce but a limited effect in most cases.

It was not until machines were applied to pump the waters, that the metals could be followed to any considerable depth, and not until gunpowder had furnished the means of splitting the hardest rock, that man was enabled to penetrate strata of every description that opposed his progress.

These inventions, therefore, form most important epochs in the history of mining; for, since mankind have called in the assistance of such powerful agents, neither the influx of constantly flowing water, nor the barriers which the most indurated rock can present, are obstacles in the way of the miner, where rich and productive veins of ore tempt the pursuit.

The first important era was the period in which the application of gunpowder to the purposes of mining took place, which happened in Hungary, or Germany, about the year 1620, and was first introduced into England at the copper-mine at Ecton, in Staffordshire, about the year 1670, by some German miners brought over by prince Rupert. It was in use in Somersetshire about 1684, and it was not until after this period, probably, that the Cornish miners became acquainted with this powerful assistant to their operations.

Its importance may be judged of by the amount of the present consumption in the mines of Cornwall alone, which has been calculated at an annual value of about forty thousand pounds sterling.

There are many mines which could not possibly have been worked without the aid of gunpowder, and, until it was used, subterranean operations must have been difficult and very uncertain. The hammer and wedges were probably the first instruments employed for splitting rocks, and the *pick* followed, which is used both as a hammer and a wedge. The change of form in these instruments observed in those which have been found in old works, as well as the materials of which they are sometimes made, offer evidence of considerable antiquity.

Many tools of oak have been occasionally met with, which tradition among the Cornish tinners make to have belonged to the Saxons or Danes, but it is probable that they were employed before the time of their having a footing in the country, and most likely when iron was little known here.

Wedges of dry wood were made use of by driving them into clefts of the rock, and then wetting them, so as to cause them to swell, and thus by repeated similar insertions to force the ground asunder.

Agricola describes the application of fire to the splitting of rocks, but there is no tradition of its having been applied to this purpose in England.

The means employed for raising or throwing up the ores and waste stuff to the surface, were at first as rude as the other operations of mining. The *windlass and bucket* may be reckoned an improvement which took place in a later stage of mining, as simple a one as it certainly is, and now in a great measure superseded by more effective machinery. It was, however, at the time an important addition to the apparatus of mines, as water as well as ore could thus be raised to moderate heights; and by the employment of much manual labour with a number of such machines, even considerable excavations were kept free from water, and had their produce lifted to the surface.

The windlass, probably, like most of the early improvements in mining, had its origin in Germany, and before it was introduced here from that country, the mode adopted for throwing up the stuff dug in the bottom of the deeper pits, was by making successive steps, or stages, which were called in Cornwall *shammels;* upon each of which men were placed, who raised the excavated matter from one to the other, until it thus reached the highest point.

In South America the windlass is even yet hardly known, and the ores are either carried up by the Indians employed in the mines, or, where the situation admits of sloping roads being made to the bottoms, are conveyed to the surface on the backs of mules.

When mines were worked deep, the labour of raising the water which was constantly collecting, became too great for mere manual exertion, and hydraulic machines were invented or employed for the purpose. Pumps were adapted to the shafts, and their constant action secured by giving motion to their pistons by wheels turned by descending streams of water. Where supplies of this agent can be obtained, and the form of the country admits of its application with considerable falls, nothing better can be desired, as it is a more regular power than steam, and infinitely less expensive; it has, therefore, continued in use to the present day, where circumstances admit of its being applied.

The German miners seem in all probability to have had the merit of these inventions, as they appear to have been completely in use among them when Agricola wrote, who fully describes their construction and application.

But though Germany may fairly claim the invention of these engines for this purpose, yet nothing more has been done there; but, on the contrary, they are said to remain now there in nearly the same state as at their original introduction. The English miner has improved the pump-work and the water-engines to their present high state of perfection in this country.

It is in some degree owing to necessity that this has been the case, as there are single mines in England which require that as much water be discharged from them, as the pumps of a whole province of German mines could effect. There is, is, indeed, no need to prove the capacity of English artists for mechanical improvement.

Hydraulic machines, however, as they require falls of water to put them into motion, can only be erected where the circumstances of a country afford the means of working them; and if nothing further had been done, many of our most valuable mines in Cornwall, not to mention our collieries and lead mines, would have remained unexplored and unproductive. The invention of the *steam-engine* gave to the miner a power capable of universal application, and of an effect that added, as it were, new regions of subterranean country to his controul. Depths hitherto unattainable are now placed at his command, and no limit can be assigned to his exertion, but that of the expence compared with the value of the produce.

The history of the steam-engine will be a subject for another place; but we may here observe, that the invention very early excited the attention of the mine owners of Cornwall, who successively adopted and encouraged the improvements of Savary, Newcomen, and Watt.

In this district some of the earliest efforts of these ingenious men were seconded and rewarded, and in return the mines have gained such assistance as could not have been formerly anticipated or imagined.

The general history of mining in England has never been very accurately traced; the districts famous for their mineral products have no communication with each other on this account, and have no common mineral laws or customs.

In other countries mining has been fostered and protected by the state, immunities have been granted, the workmen have been surrounded by particular privileges, and their operations encouraged by grants of timber from royal forests, or the free use of lands and waters. Thus peculiar systems of laws have often arisen where the mines were important as a source of revenue to the state. Something of this sort is indeed to be traced in the stannary laws of Cornwall; these laws, however, are not operative in the other mining districts England, but are confined to the counties of Devon and Cornwall, which are both included in the royal duchy which bears the name of the latter. Here the stannary laws still existing, now afford the miner but scanty assistance, though they effectually provide for the secure payment of the mineral revenue to the duke of Cornwall. To this object, and to the adjusting disputes touching the affairs of tin mines, the present administration of these laws may be said to be directed. The protection to the person of the tinner, as to military service and processes from other courts, has been gradually removed, and the rights of embounding lands for his pursuits, and of obtaining water-courses for his engines, have been questioned, and, in some cases, rendered doubtful. It cannot, perhaps, be contended that these laws could now be exercised in their former construction in the present state of property; but a revision, accommodating them to the fair wants of the miner, without prejudice to the land owner, would be attended with much benefit to the mining interest.

The copper-mines, being altogether of later date than those of tin, partake of none of the advantages which the stannary laws afford, and are therefore governed more by custom than any thing else; an extension of the privileges of the tin mines to these, and a legal provision for the peculiar arrangements which such undertakings require, would remove many serious obstacles to their prosecution.

Mining in England had a very early origin, compared with the progress of other arts in the country; it was in all probability the first source of trade to these islands, and the tin of Britain was known in distant parts of the world at a very remote period. It is generally believed that the Phœnicians were the nation principally engaged in trading to Britain for this metal. Tin works were carried on before iron was in use in England, as may be presumed from the tools of oak which have been found in ancient mines. Cicero affirmed that no silver was to be found in Britain, and though it has since been proved that he was wrong in that respect, yet the notice taken of the subject serves to shew that the metals of the country were the principal temptation to the Roman conquerors.

The Saxons neglected the pursuit of the metals, but the Normans appear to have worked for them to advantage, and from this time, until the reign of king John, the mines were mostly in the hands of Jews, when they are said not to have been successful, but in the reign ensuing they were worked by the same people with more effect. Edward I. caused the Jews to be banished, and the mines were, in consequence, neglected, until Edmund, the elder son of that king, and earl of Cornwall, willing to restore what had produced so large a proportion of the revenues of his domain, made grants important to the miner, which were confirmed by the king, by a charter in the 33d year of his reign; which states that

"For the advancement of the stannaries, he frees the tinners from all pleas of the natives touching the court, and from answering before any justices, &c. save only the keeper of the stannaries; (pleas of land, life, and member excepted) neither are they to be kept from work but by the said keeper." And it further "indemnifies them from tolls, &c., gives them libertie to dig tin and turf any where in the said countie, and to turn water-courses for their works at pleasure; with many other privileges."

It is from this time that the enactment of laws for the government of the stannaries may principally be dated.

Power to search for other metals besides tin was granted to individuals immediately from the crown, and we find that various persons held the right of searching for mines in the reigns of Edward III. Richard II. Hen. IV. and Hen. VI. In some of these grants, gold, silver, and copper are mentioned as well as lead.

The privileges of the tinners were not interfered with by any question relating to these metals, nor, on the other hand, did the jurisdiction of the stannaries extend to affairs connected with them.

Thus we find an appeal to the exchequer in the reign of Henry VI. relative to lead mines. *From the records, Easter term, anno 36. Regni. Devon Memorand.* "That John Bottwright, governor of the mines of Bury Ferrers in Devon, complains to this court that Robert Glover, at the command of Roger Champernown, took away 144 bouls of glance oar, valued at 15*l.* 6*s.* 8*d.* and made profit of the same without any thing allowed to the king, to the king's damage of 100*l.* and thereupon desireth the advice of the court."

The mines continued to be protected by the crown, and particularly by Henry VII., until Edward VI., when they were neglected; and fell into complete decay during the disastrous government of Mary.

When Elizabeth succeeded to the crown, the mines of the kingdom partook of the attention which this enterprising queen bestowed on every object from which an increase to the resources, or an addition to the strength of her government, might be derived.

The failure of the mines had diminished the number, and annihilated the skill, of the English miners; the queen therefore invited over Germans, and made extensive grants in different parts of England to Houghsetter and Thurland, and likewise others to William Humphreys and Christopher Shutz. She also established, in 1568, a corporation, which still exists, called "The Society for the Mines Royal," which had certain grants and privileges in several counties, and of which

which William, earl of Pembroke, was the firft governor. It does not appear that this fociety, which was originally a mining company, though now engaged in fmelting ores only, produced any important effect upon the difcovery of metals in England; the tin mines of Cornwall were not worked by them, but remained in the hands of private adventurers, under the jurifdiction of the ftannaries, and increafed in produce and value in proportion to the demand for this metal. The whole amount of tin annually raifed in Devon and Cornwall, in the following reigns of James I. and Charles, was from fourteen hundred to fixteen hundred tons. 'It is probable that the civil wars which fucceeded injured the workings of the mines, as in the reign of Charles II. it appears from a note of Mr. Scawen, of Molinek, who was vice warden of the ftannaries, and quoted by Dr. Pryce, that the tin revenues were very fmall.

In the reigns of Anne and George I. the produce of tin had again become confiderable, and amounted, one year with another, to fomething more than fixteen hundred tons; fo that in the fpace of 110 years its mean proportion was equal to fifteen hundred tons *per annum*.

Since the foregoing time a gradual increafe took place in the enfuing thirty years; for in the year 1742 a propofal was made by the Mines Royal Company in London to raife one hundred and forty thoufand pounds to encourage the tin trade by farming that commodity for feven years at a certain price. A committee of Cornifh gentlemen were appointed to confider of the propofal; and they reported, "That the quantity of tin raifed yearly in Cornwall, at an average for many years laft paft, hath been about two thoufand one hundred tons;" and refolved, "That three pounds nine fhillings for grain tin, and three pounds five fhillings *per* hundred weight for common tin, are the loweft prices for which fuch tin will be fold to the contractors, exclufive of all coinage duties and fees."

The produce of the tin mines was much more confiderable afterwards, and from 1760 to 1780 it was reckoned at about two thoufand eight hundred tons a-year, which was worth the annual fum of about 180,000*l*.

Copper began to be worked in Cornwall in the beginning of the 18th century, and the amount had attained at the period juft quoted to about the fame annual fum of 180,000*l*. making the mineral returns of this diftrict at this period, *viz.* about 1780, to be of the yearly value of 360,000*l*.

The tin mines have not been fo important to the Cornifh miners fince the difcovery of copper as they were before, the produce of the latter having increafed moft rapidly, while the former have not made any proportional progrefs. As the fubject is very interefting in eftimating the power of this country to fupply raw materials for its numerous manufactures, we fhall give ftatements of the produce and other particulars of the tin and copper mines of Cornwall and Devon, from the early part of the laft century to the prefent time.

We fhall firft ftate the produce of the tin mines, and afterwards give a more detailed account of the effect of the difcovery of copper on the mining intereft as well as the trade of the country.

The chief part of the tin in the following ftatement was produced from the mines of Cornwall alone, as although Devon had anciently yielded a large proportion of tin, yet before this period the mines, or rather the ftream works of the latter county had become exhaufted, and were incapable of producing any notable proportion of ore.

Account of the Quantity and Value of Tin raifed in Cornwall and Devon, from 1700 to 1800.

Dates.	Number of Blocks $6\frac{1}{2}$ to a Ton.	Number of Tons.	Price *per* Ton.	Periods.	Annual Quantity in Tons.	Annual Value.
			£. *s.* *d.*			£. *s.* *d.*
1700 to 1720	208,000	32,000		20 years	1600	
1720 to 1740	273,000	42,000	66 0 0	20 years	2100	138,600 0 0
1740 to 1750	162,500	25,000	65 0 0	10 years	2500	162,500 0 0
1750 to 1760	172,779	26,580	63 7 6	10 years	2658	168,450 15 0
1760 to 1770	177,302	27,277	66 6 8	10 years	2728	180,957 6 8
1770 to 1780	178,737	27,498	60 2 0	10 years	2750	165,275 0 0
1780 to 1790	192,295	29,583	68 2 0	10 years	2958	201,439 8 0
1790 to 1800	210,928	32,450	73 1 0	10 years	3245	227,047 2 6

From this table we may obferve a regular increafe in the quantities raifed, the improvements in mining which took place having contributed, without doubt, to produce this effect. The price of the metal did not advance in proportion to the increafe of the charges on labour, and the enhanced value of the articles ufed in the mines, and therefore we cannot account for the greater produce from increafed demand, but from the power derived by improved means of working, and thus of bringing the metal to market at a cheaper rate. About the year 1770 the quantity raifed appears to have been greater than the demand required, and the price feems to have been lower than at any former period, which was probably likewife affected by the war, and by the influx of tin imported into Europe by the Dutch from their poffeffions in the Eaft Indies, where it is raifed as well as in England. The advance in price that followed in the next period, may be attributed to the revival of trade, in confequence of the peace which followed the American war, but this again produced an over quantity in the market, followed by a depreffion in value, very injurious to the miners, which was feverely felt about 1789, when, by the exertions of Mr. G. Unwin, an export of tin to China, through the Eaft India company, took place, that abforbed the furplus which the European market did not require, and thus the price advanced again to a rate higher than any preceding one. This export to India has continued ever fince, and may probably increafe notwithftanding that tin is found in fome confiderable quantity in Afia.

From 1800 to the prefent time the tin mines of Cornwall have rather declined, and are probably gradually exhaufting, this metal not being found to penetrate fo far into the earth as copper, and therefore but few mines have been found to continue productive at very confiderable depths.

Any decline that may have taken place in the tin mines of Cornwall has, however, been more than compenfated by the

rapid

rapid advances which the copper mines have made in that and the neighbouring district, which of late years have been so great as to render them of the highest consideration, and to give these concerns the precedence over all similar undertakings of any country. For whether we consider the quantity of their produce, the immense capitals invested, the power and number of their engines, the skill with which they are conducted, or the spirited and rapid execution of the works, they will probably be found to take the rank here assigned to them.

Cornwall possesses many eminent advantages as a mining country, of which its maritime situation is among the most important, but another is that it is peopled by a race of men peculiarly fitted for this employment. The Cornish miners unite great courage to personal strength and activity, while we may observe in their character intelligence mixed with persevering enterprize, and patience of fatigue with a considerable independence of spirit.

There is no doubt but that the system of management adopted in the mines, which long usage has matured into a system as beneficial to the mine owners as stimulating to the exertions of the workmen, has tended much to render the latter what they now are, though their insulated situation has likewise probably preserved to them much of their original character as a people.

With such advantages, and with a sufficient quantity of the metallic ores distributed throughout it, a district only requires capitalists of sufficient wealth, intelligence, and enterprize, to render it of consequence as a mining country, and it has happened to Cornwall to have gentlemen possessed of all these requisites.

The statements which follow will shew how the discovery of a valuable metal has been followed up, and an intimate acquaintance with the Cornish mines would prove how great the exertions must have been, to have produced effects in a short time which the labour of ages in other countries have scarcely equalled.

We have before observed that copper began to be sought after in Cornwall about the beginning of the eighteenth century, and, as might be expected, we have no exact accounts of the success of the undertakings for its pursuit in their earliest stage. In a few years, however, the quantity produced had attained to a considerable amount, and we shall be enabled to trace pretty accurately the progress afterwards made.

The first document on the subject is the following:

Statement of the Returns of Copper Ores in Cornwall, from 1726 to 1775.

Years.	Tons of Ore.	Average Price *per* Ton.			Amount.	Annual Quantity of Fine Copper.
		£	*s.*	*d.*	£	(Probably)
1726 to 1735	64,800	7	15	10	473,500	700 Tons.
1736 1745	75,520	7	8	6	560,106	830
1746 1755	98,790	7	8	0	731,457	1080
1756 1765	169,699	7	6	6	1,243,045	1800
1766 1775	264,273	6	14	6	1,778,337	2650

This account is taken from Pryce's "Mineralogia Cornubiensis," excepting the last column of the quantities of metal produced from the ores, which it was desirable to exhibit, in order to compare the increase of late years, of which the quantity of *fine copper* is the only true criterion, the ores often differing materially in their metallic content. The statement is, however, given as respects this part of it only as a near approach to the truth, as we have no certain data to calculate from; the assay and price of copper, by which the value paid to the miner was determined, being in a great part of the period above quoted not easily ascertained. The amount of metal is, however, calculated from the most probable supposition.

From the table we see, that in Cornwall the produce of copper increased in fifty years from about 700 tons of fine metal *per annum* to 2650 tons.

Copper mines were not attended to in England much before the dates in the preceding table, the discovery of this metal probably having taken place in working the tin mines, which had been wrought time immemorial. Soon after that discovery, in 1691, a charter was granted to sir Joseph Herne and others, merchants of London, who were thereby incorporated as a company for the purposes of refining and purifying copper ores.

This company still exists, and is now commonly called the English Copper Company.

The Mines Royal Company, which had been incorporated near 100 years before this time, appear originally to have designed to apply their resources to the opening and working mines in various parts of the kingdom, and they had grants for searching for copper among other metals, although it does not appear that any important discovery of this metal took place in consequence of their exertions, nor is mining one of those pursuits which is ever likely to flourish in the hands of large companies.

In 1694, a copper coinage of halfpence and farthings took place, and government paid at the rate of 18*d.* a pound for the copper, which was of Swedish produce.

In 1717, a further coinage took place, to the amount of 700 tons of English copper, for which government paid at the rate of 15¾*d. per* pound, or 147*l. per* ton.

In 1702, the first brass work in England was erected near Bristol, which has continued to this time, but with great additions and improvements. Many other copper and brass houses have been since erected in this country, and by that spirit, energy, and enterprize, for which the people of it are so distinguished above all others, the most valuable branches of the copper and brass trade have been established in England, which had before been altogether, and for ages, carried on in Germany and Holland.

For the first twenty or thirty years of the last century, and always before, most of the copper and brass utensils for culinary and other purposes of this country were imported from Hamburgh and Holland, procured from the manufactories immemorially established at Nuremberg and various other parts of Germany; even brass pans for the purposes of the dairies of our country could not be procured but of the German make.

So late as 1745, 1746, and 1750, copper tea-kettles, saucepans, and pots of all sizes were imported here in large quantities from Hamburgh and Holland; but through the persevering industry, capitals, and enterprising spirit of our miners and manufacturers, these imports became totally unnecessary, being all made here, and far better than any other country could produce.

During all this time the price of copper will be found to have been as high as it has been in the last three or four

years;

years, 1808, 1809, 1810, and 1811, notwithſtanding the great difference in the value of money, and conſequent advance of price on materials uſed in mining, and of the wages of labour employed therein.

It appears above that government paid for copper uſed in their coinages in the year 1694 at the rate of 18*d.* a pound, or 168*l.* a ton for metal the produce of Sweden; and in 1717, they were ſupplied with Engliſh copper at the rate of 15¾*d.* a pound, or 147*l.* a ton.

The reduction here ſpecified in value may fairly be accounted for by the increaſing produce of the Engliſh mines, and accordingly the price went on to lower nearly in proportion to the quantity which was thus brought into the market.

In the year 1720 copper was ſold for about 130*l.* a ton, and declined towards the year 1772 to the price of 100*l.* a ton.

About the year 1773, new copper mines being diſcovered in Derbyſhire and Wales, and freſh ſupplies of fine copper coming from thence to market in competition with the Corniſh copper, the price of it fell gradually until 1781. In this year the Eaſt India company firſt paid ſo little as 79*l.* a ton for cake copper. This great reduction was owing to a warm conteſt which took place between the owners of the Corniſh mines and thoſe of the Paris Mountain mine in Angleſea, which had become amazingly productive, and ſo as to alarm the fears of the former.

Arrangements were afterwards made between the parties principally concerned in the mines of theſe two diſtricts, by which the price was ſomewhat advanced, but did not exceed at any time 84*l.* a ton, and continued at nearly the ſame rate until the year 1791.

By this time England, inſtead of depending upon foreign mines for a ſupply of copper, had become one of the principal ſources from which the world at large was furniſhed with this uſeful metal.

Accordingly, in the year 1791 we find that the exports of different articles in which copper either formed the whole or the principal ingredient, amounted to a very conſiderable branch of trade, and that theſe articles went in large quantities to thoſe very countries upon which England had formerly depended for a ſupply. Among theſe may be noticed Holland, Germany, and even Sweden itſelf.

The total exports were, in 1791,

	Tons.	C.	qrs.	lbs.		£	s.	d.
Wrought copper	3082	3	3	11	value	358,844	9	1
Braſs and plated goods	2324	2	0	11		209,769	8	9
	5406	5	3	22		568,613	17	10

Comparing this with the produce of copper in Cornwall in the year 1775, as above quoted from Dr. Pryce, which was only 2650 tons, and allowing for what might be brought to market from Angleſea, we may, in ſome meaſure, judge of the increaſe in the quantity of metal from the Corniſh mines in this period of ſixteen years, even under the diſcouraging circumſtance of great competition and reduced prices.

Beſides this vaſt export, a new ſource of conſumption for copper had in the mean time ariſen at home in the uſe of it very extenſively in ſheathing and faſtening ſhips, and this alone would require conſiderable quantities.

The demand having apparently kept pace with the quantity brought to market, the queſtion will naturally be aſked, how it happened that the price continued to fall, or at leaſt to remain at a rate ſo much under what it brought 100 years before? Though the anſwer to this queſtion muſt include other conſiderations than thoſe connected with mere mining, it may be proper to go a little out of our way to anſwer it, particularly as it relates to the mines of Cornwall, which were at one time threatened almoſt with ruin, from the value of their produce not bearing any proportion to the increaſe in their expences, from the diminiſhed value of money, and the rapidly accumulating charges occurring from the great depths to which moſt of the productive mines were by this time worked.

The reaſon, then, of the price of copper not bearing a proportion to the coſt of procuring it, and the demand of the article, appears to have been ſimply this. Neither the miners nor the great conſumers of the copper were ſmelters of the ore; but this buſineſs was in the hands of a very few companies, employing immenſe capitals in their works, who thus had the power of managing the market, and of preventing that ſalutary competition, which alone can regulate fairly the due courſe of trade.

The principal ſmelters, by a contract which had been entered into improvidently with them by the majority of the miners, had poſſeſſed themſelves of the greater part of the copper ores of the county of Cornwall at a fixed price; and this price being found inadequate to meet the increaſing charges of working the mines, diſcontents aroſe, which ſpread among the labouring miners, who feared the loſs of their employ by the ruin of the mines, which was anticipated. Many of the proprietors, or adventurers as they are uſually called, who were not perſonally parties to the contract, refuſed to be bound by the act of their co-adventurers, and conſiderable confuſion enſued.

The ſmall proportion of the ores, not included in the contract, continued to go to public ſale, where the price was advancing; but theſe ſales were attended by a few ſmelting companies only who had not joined the others, until the following circumſtance occurred, which materially contributed to open a free market to the miner for the ſale of his ores, upon a plan that enſures a fair and equitable price, according to the demand, as far as is poſſible, where the number of buyers muſt be neceſſarily ſmall.

Many of the principal manufacturers of Birmingham, who were large conſumers of copper, had obſerved the difference between the price of the metal in the ore paid to the miner, and the price at which they bought it when ſmelted. They ſaw no other reaſon for the intervention of a third party between the miner and conſumer, but the capital neceſſary for the erection of ſmelting works; and this being eaſily raiſed by ſhares, a company was formed under the name of the Birmingham Mining and Copper Company: their object being to encourage the production of copper, by adventuring in the mines, as well as to procure it for their manufacture, by purchaſing and ſmelting the ores.

As ſoon as the company was eſtabliſhed, they propoſed to revive the old mode of the ſale of ores, which had, owing to the contract, nearly fallen into diſuſe, called a *ticketing;* by which, on certain days, the ores of any number of mines, being previouſly ſampled and aſſayed, are offered for ſale by tenders or tickets, produced by the agents of each ſmelting company, and delivered to the chairman of the meeting which is held for the purpoſe, who declares the offer of each, and the higheſt the buyer.

This revival of the ticketings was effected by the Birmingham company joining the ſmall number of ſmelting companies who were not concerned in the contract, and the competition was rendered complete. A new ſpirit was infuſed into the working mines, by an increaſe of the price of their produce. Other ſmelting companies were afterwards formed upon ſimilar principles; and the demand for copper advancing rapidly, while the quantity produced in Angleſea and other parts of England leſſened, the mines of Cornwall flouriſhed in proportion.

The

The advance on copper began to be felt about 1792, when it had attained the price of 100*l.* *per* ton; and in a very few years after (1799), it had reached 124*l*: being still, however, much lower than it was in the beginning of the 18th century.

We may recollect that the quantity of copper raised in Cornwall, in the year 1775, was about 2650 tons a-year: in 1789 it had increased to about 3000 tons; which increase was progressive, as in the year 1797, according to the report laid before the house of commons, the quantity amounted to 5093 tons; and in the following year (1798), was 5427 tons.

So that we see in the period of about 70 years from 1726, the annual quantity produced by this district had risen from 750 to 5427 tons; and that the aggregate amount of an article, valuable as a raw material, affording, after it passes from the hands of the miner, the means of subsistence and profit to thousands, had risen from the sum of 47,350*l.* to about 600,000*l.* a-year. Even this great increase of produce was far exceeded in the course of the next eight or nine years, when, as we shall see heareafter, half as much more was added to the quantity, and more than that proportion to the value.

Early in the year 1799 the Birmingham manufacturers, finding the price of copper rapidly increasing, began to be alarmed lest a diminution of their trade should be the consequence, and having apparently overlooked the plain rule of commerce, that, without unfair restraint, demand must govern price, applied to government to impose prohibitions on the export, and other regulations, which would have amounted in effect to the fixing a maximum on the price, and consequently a ruinous restraint on a valuable source of national wealth, and laudable enterprise and exertion. It may be justly wondered at, that any ministry should have listened to such a proposal; but great as were the boasted talents of the then premier, he appears to have been led to the warm support of it, by the narrow consideration which was held out to him, of supplying the navy with copper at a somewhat lower price; not looking forward to the probability that any step which might ruin the British copper mines, must eventually make the British navy dependent on other countries for this essential article of equipment.

The contest that ensued between the miners and the manufacturers produced many curious documents, which were laid before the committee of the house of commons appointed to investigate the subject, and from which we are now enabled to state particulars of the mines of Cornwall, more exactly than could have been obtained, had not such an occasion called them forth.

The matter came fully before parliament, the good sense of which defeated the impolitic wishes of the proposers of the restrictions, and left a ministry unaccustomed to defeat in a minority on the question.

That the predictions of the manufacturers were groundless may be inferred from what took place afterwards: the price of copper advanced 50 *per cent.* in the next seven years, and the Birmingham trade, notwithstanding, increased in activity and consequence. The high price stimulated the enterprise of the miner, until an over-supply began to operate; and in the last few years, this, together with the unfortunate state of foreign trade, has again reduced the price of copper, so as once more to endanger the existence of a great proportion of the copper mines.

From the documents before alluded to, we find that, in February 1799, there were in Cornwall then working sixty copper mines, which were divided into classes, to shew their relative conditions. The accounts are made up for the six months preceding the statement.

Class 1. Includes the old deep mines, which produced in the six months more than half of all the copper raised in Cornwall.

2. Includes the profitable mines, which produced about three-eighths of the copper.

3. The new mines which were carrying on in the hopes of their improvement, and the greater number of which, in fact, had not begun to yield any ore.

The result of the statement is as follows, in which it is to be observed that the value of the ores is accounted for, after deducting the proportion paid to the owner of the soil, and therefore does not exhibit an account of all that was raised. The first column of loss refers to the money sunk in the six months for which the account is taken; and the last column of unrecovered loss includes all the money laid out from the commencement of each mine, which had not been paid off by adequate returns.

State of the Copper Mines of Cornwall for six Months, to the end of February 1799.

	Quantity of fine Copper.	Adventurers' Amount of the Value.	Cost of working the Mines.	Total of Profit on some Mines.	Total of Loss on others.	Capital employed in the Mines.	Unrecovered Loss.
	Tons. C. q. lbs.	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Class 1.—Including ten old and deep mines	1388 3 1 21	115,121 13 10	116,209 1 6	3153 0 3	4240 7 11	102,489 0 0	69,181 2 10
Class 2.—Seven profitable mines	1083 12 2 24	86,377 15 3	49,311 11 1	37,066 4 2		66,813 0 0	5483 17 2
Class 3.—Forty-three new mines, of which thirteen only had begun to raise any ores	141 17 1 13	14,517 13 3	31,813 5 9		17,295 12 6	16,267 0 0	90,124 16 8

By

By this ftatement we fee, that the total profit of the fix months, in all the mines, exceeded the lofs by the fum of 18,683*l.* 4*s.* 0*d.*, and in the lofs is included a confiderable amount, which it does not feem clear fhould have been placed there, *viz.* the fums expended on the new mines in the period, as this may more properly be called an inveftment of capital with a view to future expected profit.

The unrecovered lofs is fubject to the fame remark, though it is ufual to reckon in mining the expenditure as lofs until the profits have repaid it. The capital, however, which means the value of ftock upon the mines, ought to be deducted from this unrecovered lofs; and if this be done, and a fair allowance be made for the value of fuch new mines as might have been fuppofed likely to become profitable, the account gives no unfavourable impreffion of the general refult at that time.

Another obfervation may be made on this account which feems neceffary, as it does not appear on the face of it. Credit is only given for the adventurers' part of copper ores; but feveral of thefe mines returned tin as well as copper, of which no account is taken, and which muft, in all probability, have increafed the profits of the fix months, if ftated.

The next table fhews the general receipts and difburfements on the copper mines of Cornwall for feven years, ending the 31ft December, 1798, which cannot be deemed fo favourable as the former, which related to the latter part of this fame period.

General State of the Copper Mines of Cornwall for Seven Years, ending the 31ft of December, 1798.

Years.	Adventurers' Amount of Ores.			Labour.			Materials.			Total Coft.			Profit.			Lofs.		
	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.

1794	293,853	10	11	179,187	15	5	111,093	19	11	294,775	19	5				922	8	6
1795	305,320	6	9	189,713	10	1	111,640	2	3	312,047	7	5				6727	0	8
1796	348,836	12	11	201,995	18	6	105,925	12	1	324,897	18	4	23,938	14	7			
1797	320,606	15	9	189,821	15	11	109,008	7	3	309,060	14	10	11,546	0	11			
1798	405,488	15	9	253,601	12	3	146,253	16	3	408,248	7	11				2759	12	2
	2,237,291	10	10	1,341,478	7	0	785,405	19	3	2,195,123	2	10	62,950	11	5	20,782	3	5

N. B.—The columns of labour and materials, added together, do not make up the total coft, becaufe the accounts fent from fome mines do not diftinguifh the amount of labour from materials; and, therefore, could be no otherwife arranged than by being carried at once to the column of total coft.

The average annual coft of working the copper mines of Cornwall for this period appears to have been 313,589*l.* Out of this fum the labour appears to have coft about 197,640*l.*, and the materials employed about 115,950*l.* The proportion of the one to the other being nearly as 5 to 3.

The great amount of the latter may be attributed to the great depth of many of the mines, whereby the charge for coals for the fteam-engines, and the wear and tear in the fhafts of cordage and other articles, is prodigioufly increafed.

If, taking the amount of labour at the above fum, we allow 40*l.* as the annual earnings of each man employed, which is nearly the ufual proportion, we fhall find it would fhew that there are about 5000 men employed. But as a certain proportion belongs to the boys working under ground, and the women and children who drefs the ores on the furface, who altogether are paid after a much lower rate, the whole number of hands, including men, women, and children, may not, at this period, perhaps be over-rated at from 6 to 7000.

In order to fhew the refpective ftate of each mine at this time, we infert the following table, which exhibits the name of each, with the particulars of their expenditure and returns, as far at leaft as copper is concerned; for, as was remarked before, no notice is taken of the tin produced from any of them.

We take the year 1798, the laft of the feven years to which the ftatement given above refers to.

Such is the fluctuation of concerns of this fort, that at the prefent time, 1812, very few of thofe which appear at the head of the following lift as moft important in confequence and produce, are now working to much extent, while others, which either then lay neglected, or in which difcoveries had not been made, have fucceeded to fupply their places.

State of the Copper Mines in Cornwall for the Year 1798.

About this period a part of the county of Devon began to attract notice as a mining diſtrict, although it might rather ſeem to belong to Cornwall, if a diviſion had been made between the counties by a line that an obſerver of the geology would have chalked out, rather than by the arbitrary limit of a river. The mines of Devon may, therefore, fairly be ranked as a branch of the great mineral country adjoining, as their features are nearly alike, the products very ſimilar, and the ſyſtem of working derived from Cornwall. A ſpace of no inconſiderable extent indeed is to be found lying between the weſtern and moſt conſiderable mines in Cornwall, and thoſe on its eaſtern limits, which intervening tract is comparatively unproductive in mineral treaſures.

The tin mines of Devon have been before alluded to, and we have ſeen that they had gradually declined into inſignificance. Copper had now been found, and purſued with ſome ſucceſs, and though the quantity was not very great at this period, it ſoon led to greater exertion, which in turn was repaid by the diſcovery of new mines and an enlarged return of valuable produce.

It is probable that before 1800 the mines of Devon, which are moſtly ſituate within a few miles of the town of Taviſtock, did not yield more in any one year than about 100 tons of fine copper, and even this was a very recent diſcovery; we ſhall now ſee that they went on, together with thoſe of Cornwall, augmenting in importance.

From 1798 to 1804, the produce of the Corniſh mines appears to have continued pretty ſteadily at about 5500 tons of fine copper a-year; while the Devon mines in the ſame period increaſed their returns very rapidly, which had reached, about this time, to about 300 tons of fine copper a-year.

The price of the metal we mentioned to have been, in 1799, about 124*l.* a ton, and until 1804 a gradual increaſe was experienced, although the ſupply was at leaſt ſomewhat larger. In the following year, however, owing to the flouriſhing ſtate of the export trade, the value of copper roſe very rapidly, and reached the unprecedented price of 180*l.* a ton to the miner. The conſequences of this were ſoon felt, and, by the exertion produced by this ſtimulus, the returns of the Corniſh and Devon mines reached to more than 7000 tons of fine copper, fetching, at the firſt hand, the ſum of 1,260,000*l.*

From this time to the preſent, the value of copper has experienced violent and rapid fluctuations, being, at one time, at half the price of the year 1805; and as this has proved a cauſe of great embarraſſment and loſs to the adventurers in the mines, ſo it has tended to reduce again the quantity of copper raiſed.

The year or two following 1805 were, as might be expected, even more productive than that in which the price attained its higheſt pitch, for the exertions it cauſed operated long after the price began to decline.

The following Table exhibits a Statement of the Quantity of Copper Ores and Fine Copper produced by the Mines of Cornwall and Devon during the last four Years, taken up to the End of June in each Year, and the Value calculated according to the Average Standard, or Miner's Price of the Metal.

		Copper Ores.			Fine Copper.				Average Standard *per* Ton.			Annual Amount after deducting Charges of Smelting.

We have now brought the history of the copper mines up to the present period, and we have found what has been done in one district in the space of about 100 years after the discovery of the metal. We may observe, that in the beginning of the 18th century the annual produce of the mines consisted of about 6500 tons of ore, and 700 tons of fine copper, yielding to the miners, who, from their ignorance of the subject, did not then receive from the smelters a price for their ores adequate to the value of the metal they contained, no more than 45,000*l.* a-year. And we have found this produce increased, at the early part of the present century, to the annual quantity of near 80,000 tons of ore, yielding more than 7000 tons of fine copper, worth to the miners an annual sum little short of 1,000,000*l.*

The copper mines now working in Cornwall and Devon may be known from the following list, which contains such only as are more or less productive, and does not include such as make no returns, but may, notwithstanding, be prosecuting with a view to future discovery, many of which kind were stated in the former account of the mines working in Cornwall in 1798.

By referring to that statement, we shall find the productive mines to be forty in number, and the unproductive to amount to thirty-six.

The following list will be found to contain sixty-one productive mines, with the quantity of ores estimated from the account of sales at the ticketings, where the computed weight of each parcel of ore is stated, and the exact quantity determined after the sale has taken place.

It is possible that some few mines may exist which do not appear in this list, and which sell their ores by private contract, but they are not important.

We subjoin to the list the Devon mines, with their quantities of ore, taking account, as in Cornwall, of such only as are productive; and the whole is made up to the end of December 1811.

A list of Copper Mines, with the Quantities of Ore offered for Sale at the Ticketings from each, in the Year 1811.

In the county of Cornwall there are 61 mines.

Hence it will appear, that the copper mines have of late been declining in their produce, which is to be referred to the general ftate of trade rendering the price of the metal unequal to the charge of producing it.

The prefent value of copper, as was obferved in a former part of this article, is as low as it was 100 years ago, and we may account for the poffibility of this happening without abfolute ruin to the mines, by the facilities which the great improvements in all the various operations of mining have given for leffening manual labour and confequent expence.

This very improvement has, however, contributed to a more rapid exhauftion of the ores, and though difcovery has hitherto in this diftrict kept pace with the gradual wafte, yet it is impoffible not to forefee that as the country is even now very fully explored, a time muft arrive when the quantity of metal produced will grow lefs, and the price in confequence muft advance.

This period we conceive is not fo diftant as fome may imagine, but it is a fubject not eafily reduced to any very probable calculation.

The hiftory of the mining of a particular diftrict would naturally lead to an interefting enquiry on this fubject, and to the difcuffion on the probability of a future and continuing fupply of the metals which the bowels of the earth have hitherto yielded fo abundantly. As this queftion regards one country, it may be affumed that the fupply muft have its limits; as it regards the whole world, it becomes difficult even to conceive what extent or number of depofits of metal may exift.

That certain diftricts may become exhaufted is more than probable, but others now unexplored by the hand of man may be found. New powers, as far furpaffing thofe of the fteam engine as they did all former ones, may give the means of penetrating the earth to depths now unattainable, and veins may hereafter be followed to fituations which are forbidden at prefent by the value of their produce or the want of fufficient exertion.

The ftores which the earth yields from its bowels are unlike thofe which its furface produces; the former are limited and are not renewed, the latter are conftantly produced by the encouraging hand of induftry. The one are gradually exhaufting, and feem to demand frugality in their expenditure, the other grow and increafe in proportion to our care and exertion.

The refult of a gradual exhauftion of mines now exifting feems likely to be this; at firft the price of metals will increafe in proportion to their fcarcity, this advance in value will lead to a greater produce by new efforts even in the diftricts which are exhaufting, and after thefe begin again to fail, which they will do more rapidly from the increafed exhauftion, new diftricts will be fought after, and perhaps uncultivated countries even become peopled by the want of what is now become fo neceffary to human life.

The variation in thefe affairs may at fome time make material changes in the ftate of civilization, a pofition which will not be denied by thofe who duly confider the effects that the ftores of coal and metal have had on the profperity of Britain.

Mining *Proceffes*, according to the practice of the mineral diftricts of Cornwall and Devon.

The means purfued for the difcovery of veins containing metal, and the appearances which ferve as indications of the probable quantity which may be found in them, are treated of in a former article. See Lode.

The works which follow the difcovery are at firft but fimple and limited, but they increafe afterwards in proportion as the profpects of future fuccefs become more certain; or, on the contrary, they are difcontinued when the trial offers but little encouragement to proceed with the adventure.

By a reference to the article above quoted, it will be underftood how the depofits of metal are ufually fituated in the veins; and as the miner's object in his firft operations is to get at fome fhoot or bunch of ore as quickly as poffible, and to open as much of the lode as he conveniently can, the moft promifing part on the furface is chofen for the commencement of a *fhaft*, which is either funk upon the vein fo as to follow its dip or underlay, or otherwife is carried down perpendicularly from fome fpot on the fide to which it dips, fo as to interfect it at a given depth, and then is ufually called an *underlayer*.

As water is commonly foon met with in fuch quantities as to impede the workmen, means for removing it muft be provided, and it fpeedily becomes neceffary to take fteps for this purpofe. Where the elevation of the ground will admit of an *adit* or water-level being made, this is ufually firft had recourfe to, particularly when it may be obtained by driving a moderate a moderate distance, or when it can be pursued on the course of the lode, and so serve the double purpose of a drain and a level for trying the appearances of the vein.

When the shaft becomes deeper than the adit, or indeed when the latter cannot well be had, machinery to draw out the water is erected and employed, such as steam-engines, or overshot water-wheels where streams to drive them can be obtained: in both cases these engines are employed to work pumps to raise the water.

As soon as a shaft is sunk sufficiently deep, and it becomes desirable to pursue the lode horizontally, it is stopped for a time, and a level is commenced on each side of it, and this is usually continued in two opposite directions upon the course of the vein. The ends of this level being driven out of the way of the shaft, sinking may again be undertaken, and continued until it is deemed proper to drive another level; and thus a succession of these galleries or drifts are opened under each other, and the vein is divided into parallel portions, which are left to be worked for the ore contained therein, and which portions are called *backs*.

New openings to the surface from these levels are afterwards made by sinking more shafts at proper distances, and communications from one level to another are formed by sinking a kind of small underground shaft, called a *winze*, probably because the only machine employed in their execution for hauling the stuff is the common windlass, which, in Cornwall, has generally the same abbreviated or corrupt appellation.

When a mine is put into this state, and any quantity of ore discovered, proper engines provided with sufficient power to admit the constant deepening of the mine by keeping the bottom of the engine shaft, called the *sump*, dry, so as to be regularly sinking: when the ventilation is completed by proper means for that purpose, and machines constructed for hauling up the ores and waste to the surface called *whims*, a mine, in the technical language of Cornwall, is said to be in due course of working.

The agents who attend daily to the works are called *captains*; they contract with the different classes of miners, and direct the operations, under the orders either of the principal adventurers, or a manager appointed by them.

The shafts and levels are kept regularly sinking and driving to lead to further discovery, or to open more of the lode for working, and the parts of the vein or lode left between the passages thus made are worked away, where the ore will pay the expence of so doing, by men, who contract for this work within certain limits, being paid a proportion of the value when merchantable, which is called a *tribute*, and which varies with the degrees of facility with which the ore can be procured, either from the different states of richness of the lode, or the hardness or softness of the rock which must be broken to obtain it.

The ore is usually conveyed in wheelbarrows through the levels under ground by boys to the nearest shaft, and there raised in buckets or *kibbles* to the surface. These kibbles are wound up by the whims, which are turned either by horses, steam, or water.

In preparing the ores for smelting, a variety of processes is employed, which require the labour of many hands; these are carried on upon the surface, and chiefly by women and children. The object being to separate from the ore both the stony and sparry waste, and the mundic or other useless metallic mixtures with which it is combined, considerable skill is required, from the different specific gravities of the various substances, which render it impossible by mere washing to separate the ores entirely from the different mixtures which accompany it.

To dress ore properly, it is essential that the whole should first be brought into such a state of division, that the different parts may be separated by washing or sifting: and, therefore, the richer the state in which the whole is raised from under ground, the less the labour required in breaking or stamping. The better parts of the ore are broken to a proper size for smelting, either by flat hammers, or, as is now usual in the mines in Devon, by iron cylinders driven by water. For the coarser parts much more labour is required in stamping, sifting, and washing, the particular detail of which will be found under the article ORE.

The stamping-mills, and other apparatus for dressing the ores, are usually fixed as near the mouths of the shafts on the surface as possible, consistently with the power of leading streams of water to them. And plots, or *floors*, are prepared near them for receiving the merchantable ores until they are sold to the smelting companies.

The management of these processes is usually confided to a *dresser* or *grass captain*, who regulates the whole, the expence being borne by the men who raise the ore on tribute, who take their proportion of the value according to the amount of the sales, and, therefore, pay every previous charge.

The erections on the surface of a mine comprize, besides steam or water-engines, whims, stamping-mills, and sheds on the dressing floors, a suitable counting-house for the captains and clerks, where the people are paid monthly, and the bargains or contracts made by a kind of public auction. A forge, or blacksmith's shop, accommodated to the extent of the mine, where men are generally at work by night as well as by day, to sharpen tools as well as to make or repair the iron-work of the different engines. A carpenter's shop, or *timber-house*, for work of that description, which is always going on to a considerable extent.

From the account given in the *History of* MINING, and the statement of the disbursements and returns there exhibited of all the concerns of that description in Cornwall and Devon, it may be seen how extensive some of them are in that respect. It may further be here observed that great depth has been attained in many of the older ones; in Dolcoath, which we believe is rather the deepest, the lowest part is somewhat more than 220 fathoms from the surface. Some individual mines in Cornwall employ near 1000 persons, and have several steam-engines working for the different purposes of pumping the water and raising the ore. In the county of Devon, streams of water being at hand, large over-shot wheels are employed for working the pumps, and several have been erected of late years equal in power to the larger steam-engines. Within a very late period, the same economical means have been applied in a very ingenious manner to the winding up the ores from under ground, which, from the crookedness of the shafts of copper mines, was a work of more difficulty than might at first appear.

We propose to give more detailed accounts of the processes of breaking, raising, and dressing the *Ores*, under the article bearing that title; and shall describe the operations of sinking shafts and driving the levels from them under the head of SHAFT. The pump-work of mines, and the means for ventilating drifts, will be treated of in their proper places.

MINION, in *Geography*, a small island in the straits of Mozambique, near the W. coast of Madagascar. S. lat. 12° 40′. E. long. 49° 32′.

MINION, a sort of cannon, or piece of ordnance, of which there were formerly two kinds; large and ordinary, answering to our six-pounders. See CANNON.

MINION is also the name of a type used by printers.

MINISH, or Mynish, in *Geography*, one of the many iſlands on the weſt coaſt of the county of Galway, Ireland. It belongs to the barony of Ballinahinch.

MINISINK, a town or rather village of America, in New Jerſey, in the N.W. corner of the ſtate, and on the W. ſide of Delaware river; 57 miles N.W. of Brunſwick.—Alſo, a townſhip of Orange county, New York; containing 3594 inhabitants.

MINISTER, one that ſerves or conducts the public worſhip of God.

In the reformed church, prieſts, or thoſe ordained to preach and do the other functions of the prieſthood, are called abſolutely and ſimply miniſters.

In which ſenſe, biſhops, &c. are ſaid to be miniſters of God, miniſters of the Word, of the Goſpel, &c. In ſome churches they are alſo called *paſtors*.

Ministers *of the Altar* are properly thoſe who attend and aſſiſt the prieſt at the adminiſtration of the euchariſt. See Deacon and Subdeacon.

Officers of ſtate, &c. are called the king's miniſters; as adminiſtering the affairs of juſtice, policy, &c. for him.

Minister *of State*, is he with whom a prince entruſts the adminiſtration of his government; or to whom he commits the care and direction of the principal affairs thereof.

Boethius is propoſed as a model for miniſters of ſtate.

The grand vizier is the prime miniſter of the Ottoman empire.

Ministers, *Foreign*, or the miniſters of foreign princes, are their ambaſſadors, envoys, agents, or reſidents in the courts of other princes.

There are two kinds of foreign miniſters. Miniſters of the firſt rank, who are alſo called *ambaſſadors*, and *envoys extraordinary*.

And miniſters of the ſecond rank, who are the ordinary reſidents.

Thoſe of the firſt rank have a repreſentative character, which the others have not; though theſe laſt are ſometimes inveſted with fuller powers than the former.

Minister is alſo the title which certain religious orders give to their ſuperior.

In this ſenſe we ſay, the miniſter of the Mathurins, or Trinitarians.

Minister, among the *Jeſuits*, is the ſecond ſuperior for each houſe; thus called, as being an aſſiſtant to the ſuperior, or rector.

The general of the Cordeliers order is alſo called the *miniſter-general*. See Jesuits.

MINISTRY, or Ministery, a profeſſion, office, or employment, which a perſon diſcharges for the ſervice of God, the public, or ſome particular perſon.

In which ſenſe we ſay, a biſhop muſt account to God for his miniſtry, &c.

Ministry is alſo uſed for the government of a ſtate, by ſome great miniſter, under the ſovereign authority.

In which ſenſe we ſay, the miniſtry of the cardinal de Richelieu, &c.

Ministry is alſo frequently uſed as a collective word, ſignifying the miniſters or officers of ſtate.

Thus we ſay, the miniſtry oppoſed a thing; meaning the miniſters oppoſed it.

MINITOBA, in *Geography*, a lake of Canada, 100 miles long, and from 10 to 15 wide. N. lat 50° 40′. W. long. 100 20′.

MINIUM, in the *Natural Hiſtory of the Ancients*, a name given to what we now call cinnabar, or native mineral of a ſhining red colour, out of which quickſilver was extracted. See Mercury.

As the prepared cinnabar is much preferable to the native as a pigment, it has long been a conſiderable article of chemical manufacture; and the Dutch having had the reputation of making the beſt, we ſhall ſubjoin their method of proceeding, given by M. Tuckert (Ann. de Chem. iv. p. 25.) cited in Aikin's Dictionary. This manufacture conſiſts of two diſtinct operations, the one being the preparation of the æthiops, the other the converſion of the æthiops into cinnabar. To make the æthiops, a boiler of iron poliſhed on the inſide, and about $2\frac{1}{2}$ feet in diameter, and 1 in depth, is charged with 1080lbs. of mercury, and 150lbs. of ſulphur (or *per cent.* 87.8 mercury, and 12.2 ſulphur); a moderate heat is then applied gradually increaſing, and accompanied by ſuitable ſtirring of the ingredients till the whole appears to be thoroughly mixed and combined. The black ſulphuret of mercury thus formed, is then removed from the boiler and pulverized. In order to convert this into cinnabar, three large earthen ſubliming pots are placed in a furnace, and gradually brought to a red heat by means of turf: at this time the cover of each (which conſiſts of a ſimple ſquare plate of iron) is removed, and the contents of an earthen veſſel, holding about a pint and a half of æthiops, are poured into each pot. In a few ſeconds a column of flame riſes out of the pots, to the height of five or ſix feet, and, as ſoon as it begins to leſſen, the further eſcape of the contents is prevented by putting on the iron cover. In a ſhort time after a ſecond charge is poured in, to which ſucceeds a third, and ſo on, till at the end of thirty-four hours the whole of the æthiops has been equally divided between the three pots, making 410lbs. for each. The fire is now kept up as ſteadily as poſſible for thirty-ſix hours longer, in order to accompliſh the ſublimation, care being taken to ſtir up the materials at the bottom of the veſſels at leaſt once every half hour, by an iron rod made for the purpoſe and introduced at the top. At the ſame time the workman aſcertains how the proceſs is going on by the flame which appears when the cover is removed; if it riſes to the height of two or three feet, the heat is too great, as on the other hand it is too feeble if the flame only lightly quivers about the mouth of the pot; the proper temperature is marked by the flame riſing vigorouſly, yet not exceeding three or four inches in height. When the laſt thirty-ſix hours are expired, the furnace is extinguiſhed, and the whole allowed to cool: the ſubliming pots are then taken out, the iron hoops with which they are bound are knocked off, and the pots themſelves are broken; the cinnabar is found ſublimed in the upper part of the veſſel to the amount of 400lbs. being 10lbs. leſs than the æthiops that was put in: or, in other words, the loſs of weight ſuſtained by the converſion of æthiops into cinnabar, amounts to $2\frac{1}{8}$ *per cent.*

Minium, or red lead, is a calx of lead of a vivid yellowiſh-red colour, which colour it acquires by a ſlow calcination and reverberation.

The method in which minium is made in large quantities with us, is conciſely deſcribed in our article Lead.

The proceſs by which minium is prepared is deſcribed in the following manner by M. Jars. The furnace is of the reverberatory kind, with two fire-places at the ends; each fire-place being ſeparated from the area, or body of the furnace, by a wall twelve inches high. The fire-places are fifteen inches broad, and their length is equal to the breadth of the whole furnace, which is about eight or nine feet. The length of the area from one place to the other is nine or ten feet. The quantity of lead uſed in one operation is about 1500 pounds, of which nine parts are lead obtained from furnaces where the ore is ſmelted, and one part is lead extracted from the ſcoria which is formed in ſmelting the ore. This

This latter kind is said to be necessary, as the former could not alone be reduced into powder. All the lead is at once put into the area, the bottom of which is level. The calx, as fast as it is formed, is drawn to one side by means of a rake suspended by a chain before the mouth of the furnace. In four or five hours the whole quantity of the lead is calcined; or, if any pieces remain uncalcined, they are separated and kept for the next operation. The heat employed is that of a cherry-red, and the fire-places and mouth are kept open, that the air may accelerate the calcination. The powder or calx is to be frequently stirred to prevent its concreting, and when this operation has been continued about twenty-four hours, the matter is taken out of the furnace, and laid on a flat pavement. Then cold water is thrown on it, to give it weight, as the workmen say; but rather (as M. Jars thinks) to make it friable. It is then to be ground in a mill, and the finer part is separated by washing, while the coarser part, reserved for some following operation, is to be placed at the mouth of the furnace in order to retain the melted lead. The fine powder, which is now of a yellow colour, is again put into the same or a similar furnace, and exposed to a very moderate fire, from thirty-six to forty-eight hours: during which time it is stirred frequently to prevent its concreting; and the powder gradually acquires its proper red colour. The minium is then to be taken out of the furnace, cooled, and sifted through an iron sieve placed in a cask. Mem. de l'Academie Royale à Paris, 1770. In Holywell, Flintshire, minium is made from litharge, which saves the previous calcination.

A portion of the lead during the operation is lost by volatilization; part of it being dissipated in the air and part settling in the chimnies, and on the roofs of the furnace, in form of a yellowish-white soot, with crystallized lumps intermixed: this is collected from time to time, and either reduced into lead, or mixed with the lead in the subsequent calcination. The quantity of sublimate thus collected cannot be accurately ascertained. Dr. (bishop) Watson, in his "Essays," estimates it at about $\frac{1}{480}$dth of the minium produced. From the circumstances above recited it is not possible to determine the full increase of weight which lead should acquire by its conversion into minium. On an average the actual increase is about $\frac{1}{10}$th; 20 cwt. of lead producing 22 cwt. of minium.

Minium, in the *Materia Medica*, and the *Arts*, &c. For medical purposes it is used externally; it obtunds the acrimony of the humours, allays inflammations, and is excellent in the cleansing and healing of old ulcers: it is used on these occasions in many of the plasters and ointments of the shops; it is an ingredient in the officinal composition, called *emplastrum de minio*, used as a deficcative and cicatrizer; though more rarely than that made in the same manner with litharge, because it does not stick so well, and is more difficult of preparation. See Emplastrum, Lead, in *Medicine*, and Unguent.

It was with minium the ancient Roman and Grecian ladies tinged their nails and faces of a red colour. For, as to our modern paints, without doubt, they were not known in those days.

The bright orange colour of minium might render it valuable in painting, if it could stand with certainty in either oil or water. But as it is subject to become black, it cannot be safely trusted, except in hard varnishes: and is, therefore, seldom used in oil, or even in water, unless for very gross purposes, or as a ground for vermilion. The goodness of the minium may be distinguished by the brightness of its colour: and the adulteration to which it is liable may be detected, by putting an ounce of it into a crucible, with an equal quantity of charcoal-dust, well mixed together, and placing the crucible in a common fire sufficient to melt lead, which is to be covered with another small crucible inverted into it. When it has been continued for some time on the fire, take it out and strike it against the ground, the minium will thus be reduced to its metallic state; and its diminished weight, when freed from the charcoal-dust and cold, will indicate the proportion of adulterated matter. Minium is also used as a flux in forming the enamel for grounds, and in glazing, &c.

MINNIGAFF, in *Geography*, a town of Scotland, in the county of Kircudbright; 15 miles S.W. of New Galloway.

MINNIN, a stringed instrument of music among the ancient Hebrews, having three or four chords to it. Though there is reason to question the antiquity of this instrument; both because it requires a hair-bow, which was a kind of plectrum not known to the ancients, and because it so much resembles the modern viol. Kircher took the figure of this, the *machul chinnor*, and *psaltery*, from an old book in the Vatican library. Hawkin's Hist. Music, vol. i. p. 255.

MINO, in *Geography*, one of the smaller Philippine islands, near the E. coast of the island of Bool. N. lat. 10° 6'. E. long. 124° 30'.

MINOMEIT, a town of Prussia, in Oberland; 13 miles W.N.W. of Heilsperg.

MINONG, or Isle Royal, an island of Canada, in lake Superior, 30 miles long and 10 broad. N. lat. 48°. W. long. 89°.

MINOR, a Latin term, literally denoting *less*, used in opposition to *major*, greater.

Thus we say, St. James Minor, Asia Minor, the minor excommunication, &c.

Minor *Ædilis*. See Ædile.
Minor *Anticus Serratus*. See Serratus.
Minor *Barons*. See Baron.
Minor, *Canis*. See Canis.
Minor *Gastricus*. See Gastric.
Minor *Oculi Obliquus*. See Obliquus.
Minor *Orders*. See Orders.
Minor, *Rectus*. See Rectus.
Minor, *Teres*. See Teres.
Minor, *Ursa*. See Ursa.

Minor, in *Law*, denotes a person under age, or who, by the laws of the country, is not yet arrived at the power of administering his own affairs, or the possession of his estate.

Among us, a person is a minor till the age of twenty-one; before which time his acts are invalid. See Age and Infant.

It is a maxim in the common law, that in the king there is no minority, and therefore he hath no legal guardian: and his royal assents and grants to acts of parliament are good, though he has not in his natural capacity attained the legal age of twenty-one.

The minority of the kings of Sweden, Denmark, and the provinces of the empire, terminates at eighteen years; and that of the kings of France at fourteen, by an ordonnance of Charles V. in 1374.

It is also provided by the custom and law of parliament, that no one shall sit and vote in either house, unless he be twenty-one years of age. This is likewise expresly declared by stat. 7 & 8 Will. III. cap. 25. with regard to the house of commons.

Minor, in *Logic*, is the second proposition of a formal or regular syllogism, called also the assumption.

Minor, in *Music*, is applied to certain concords, which differ

differ from, or are lower than, others of the same denomination by a lesser semitone, or four commas.

Thus we say, a third minor, or lesser third: or a sixth major and minor.

Concords that admit of major and minor, *i. e.* greater and less, are said to be imperfect concords.

MINORS, or *Friars Minors*, an appellation which the Franciscans assume, out of show of humility; calling themselves *fratres minores*, i. e. *lesser brothers*; and sometimes Minorites.

There is also an order of regular Minors at Naples, which was established in the year 1588, and confirmed by Sixtus V.

MINORBINO, in *Geography*, a town of Naples, in the province of Bari, the see of a bishop; 85 miles S. of Naples. N. lat. 41° 5'. E. long. 15° 59'.

MINORCA, INSULA MINOR, the lesser, when compared with Majorca, and the second of the Balearic isles, an island of the Mediterranean, is long and narrow, forming part of a circle from the S.E. end to the N.W., the hollow part being towards the S. It is thought to be 13 leagues in length at the longest part, and near 38 leagues in circumference; it lies about ten leagues to the N.E. of Majorca, and 50 E. from the mouth of the Ebro. Minorca has successively fallen under the dominion of the Carthaginians, the Romans, the Vandals, the Moors, the Aragonese, and the Castilians; and for a century, from 1708, it has been in the possession of the house of Austria, the English, French, and Spaniards, by turns. This island is situated in the middle of a number of small rocks, banks, and islands; on the south the shore is level. The air is moist, and the soil dry. The administration is divided into districts, or terminos, the chief towns of which are Ciudadella, Mahon, Alayor, Ferarias, and Mercadal. The principal ports are Mahon, on the E.; Fornella, on the N.; and Ciudadella, on the W. The isle is level, and there is only one mountain distinguished by its elevation, *viz.* Monte Toro. Ciudadella, or Samna, the capital, is situated at a small distance from the coast, towards the N.W., 11 leagues from Mahon; it was in the fifth century the see of a bishop, and the residence of the governor of the island, and also the seat of civil and ecclesiastical jurisdiction. In the time of the Carthaginians and Romans it was a considerable place; but its splendour has declined; and port Mahon disputed with it the superiority, when the English established their tribunals and seat of government in the island. (See PORT *Mahon*.) The port is small and marshy, formed by a canal, bounded by rocks. On the right and left are towers, corresponding to each other, to repeat the signals, and two cannons of a large calibre, upon swivels, sufficient to stop a privateer. The entrance is difficult of access. The city is surrounded in part with ancient walls, erected by the Moors; the rest is modern, formed of bastions and curtains of hewn-stone. The streets are of ancient form, being narrow and shady, paved with large unhewn stones; and in the city are a cathedral, flanked by a beautiful square tower, and supposed to be built in the third century, two churches, three convents, and an hospital. The termino, of which Ciudadella is the capital, bearing its name, is above 5½ leagues long, and 2¾ wide; and its total population amounts to about 800 persons. Alayor is situated about 4½ leagues from Mahon, being the chief town of the termino of that name, containing about 112 hamlets or manors, and rather more than 4000 people. The streets are uneven, narrow, crooked, and ill paved: but the houses are well built. At the entrance into the town is a church, built of free stone, in a simple Gothic style of architecture without, and within decorated with sculptures and paintings. The monastery of Cordeliers has a handsome church. Here are also an hospital, and a barrack capable of accommodating 250 men. The town is well provided with cisterns, and the water is fresh and salubrious. About one league from Alayor is *Mercadal*; which see. The most remarkable ports of this island, besides those of Mahon and Ciudadella, are Fornella and Adaya. Port Fornella is about six miles from mount Toro, of a circular form, with a narrow entrance, and facing the north. The bay is capable of containing the largest fleet, perfectly sheltered, and defended at the entrance by a small square fort, with bastions and fosses. The establishment is capable of containing 300 men. The entrance to the port of Adaya is concealed by eminences towards the north; it is only used for fishing. The strength of the island depends upon circumstances. When the English retook it, in 1798, the Spaniards had in it 6000 troops, and the English, exclusive of their naval force, disembarked only 3000 soldiers. When the Spaniards, four years after, were reinstated, they left a garrison with 3000 infantry, 1500 light infantry, 500 engineers and miners, and 90 heavy cavalry.

Of the islands, or islets, surrounding Minorca, the most considerable are to the S., about ¾ of a mile from Cabo Bufara. The island of Coloms is elevated, and forms with the cape a narrow canal. Near it are two small islets. The large and small islands of Adaya are near the port of the same name. To the S.E. is situated the large island of Aguila. The isle of Sanitge is near the port of the same name on the W. coast; at some distance is an islet, and beyond that the island of Bleda. Beyond the rocks of Alayor, are a small island named named Galera, and an islet called Codrell. The isle of Layre de Mahon is within reach of the ancient fort of St. Philip, and there are several small islands near Mahon.

Monte Toro is at a little distance from Mercadal, and by its elevation commands the whole island: at its base it is some miles in circumference, and its form is that of the frustum of a cone. Mount St. Agatha is situated N.W. of Mercadal, and rises above several mountains that surround it. Upon the summit is a chapel, held in great veneration. The whole of this canton is inhabited by shepherds, whose flocks subsist upon a part of the mountains, and the valley beneath is abundantly fertile.

Minorca is not sheltered from the north winds, which check vegetation; nevertheless snow is seldom seen here in winter, and in the spring the air is always temperate and pure; the heat of summer is great, and the drought is productive of inconvenience. In the autumn there is much rain. The soil of the plains is less fertile than that of the coast; and the earth upon the mountains, though thinly spread over the rocks, is rich and fertile. In the vallies and plain, the soil is argillaceous and thin, but it is fertilized with that which is washed down from the mountains. Upon the whole, this island is, in many parts of it, rich in vegetation. The principal grains cultivated in the island are wheat, barley, and a small quantity of maize. Red and white wines are exported; olive trees are numerous, and here is abundance of every kind of fruit, such as oranges, pomegranates, lemons, figs, &c.; and the island furnishes great variety of garden and culinary vegetables. The water-melons are very fine; and the honey of the island, some of which is exported, is reckoned very good. The horses, mules, and asses, are estimated at about 2000; the horned cattle at 7000; the sheep, goats, and small animals, at about 45,000; the pigs at nearly 10,000. Poultry is scarce, but birds of different species are very numerous. The fish all round the island is abundant at all seasons, and very good. The inhabitants have

have no manufacture or fabric for furnishing articles of exchange in commerce. Their export trade consists of a small quantity of cheese sent into Italy, and a small surplus of wool, which produce about 2500*l.* sterling; salt, wine, honey, and wax produce from about 17,083*l.* to 17,292*l.* The island receives from abroad corn, brandy, rice, sugar, coffee, tobacco, spices, linen, fine cloths, boards, pitch, cordage, &c., and some pieces of furniture. The natural history of this island presents to us a natural and very interesting grotto, called La Cava Perella, two miles to the S. of Ciudadella; and also a subterranean lake; a quantity of coral is found near the sea-shore, and a small variety of shells. In many parts of the island are mines of iron and lead, and quarries of stone and marble. The inhabitants are a quiet, peaceable people, attached to their own customs, and little disposed to change. They regard with reverence the ceremonies of religion. The same language is spoken in Minorca and Majorca. In this island, and particularly in the territory of Alayor, they have some altars of ancient date. It has also furnished Phœnician, Macedonian, Carthaginian, Celtiberian, Grecian, Roman and Spanish medals, in gold, silver, and large and small bronze. In this island, also, a small Gothic bronze coin has been discovered, the impression on which is a crowned head in the centre of a circle, with these words, "Alphonsus Rex;" supposed to belong to the end of the 13th century. The island also has presented to the antiquarian ancient sepulchres, vases, lamps, urns, lacrymatories, composed of a reddish earth, and marked with illegible inscriptions. N. lat. 39° 59′. E. long 3° 45′.

MINORCA, *Cape*, a cape on the E. coast of Majorca. N. lat. 39° 50′. E. long. 3° 12′.

MINORE, Ital., the same as *minor*, Engl.

MINORESSES. See *St.* CLARE.

MINORI, in *Geography*, a town of Naples, in Principato Citra, the see of a bishop, suffragan of Amalfi, near the sea; three miles N.E. of Amalfi. N. lat. 40° 37′. E. long. 14° 26′.

MINOS, a small island near the coast of South Carolina. N. lat. 33° 48′. W. long. 78° 38′.

MINOS, *Los*, a town on the N. coast of Masbate, one of the Philippine islands. N. lat. 12° 33′. E. long. 123° 10′.

MINOS, in *Mythology*, one of the three judges of hell, of rank superior to the other two, *viz.* Æacus, who, according to Plato, judged the Europeans; and Rhadamanthus, who, having left Crete, and fixed his residence in Asia, had the Asiatics and Africans for his lot; and Minos, as chief president of the infernal court, decided the differences that arose between the two other judges. All the poets are agreed in assigning to him the superiority over his colleagues. Homer represents him as sitting with a sceptre in his hand, in the midst of the ghosts of departed mortals, who plead their respective causes in his presence. Virg. Æn. vi. v. 432, places an urn by him, containing the several lots of mankind; while the stern Rhadamanthus sees to the execution of the sentences which his brother pronounces. The particular district of Ades, over which he was supposed to preside, was Erebus: and it was his office to determine the character and final condition of the spirits cited to his tribunal. Minos, it is said, was the first king of Crete, and considered as the wisest legislator of antiquity; on which account he obtained the honour of being judge in the invisible world. This Minos, whose institutes are said to have served as a model for those of Lycurgus, flourished, according to Selden, and others, who refer for authority to the Arundelian marbles, 1462 years, but, according to the abbé Banier, only 1340 years before Christ.

Minos, with a view of giving greater authority to his laws, retired into a cave at Crete, where he feigned that Jupiter, his father, dictated them to him, and every time he returned from the cave he announced some new law. Hence, Homer (Odyss. 19.) gives him the title of Jupiter's disciple, Διος μεγαλου ὀαριστης, which is thus expressed by Horace (Odyss. 10.), "Et Jovis arcanis Minos admissus." Josephus is the only ancient writer, who says that Minos had received his laws from Apollo, and that he had travelled to Delphi to receive them from that god. (Lib. ii. against Appian.) This Jewish writer owns, that Minos was the only one among the ancients who deserved to be compared to Moses. If we give credit to Huetius, Minos was the same with Moses, and he alleges that they lived about the same time. But the opinion of the learned prelate is contradicted by the decisive testimony of all antiquity; nor is the parallel which he has ingeniously drawn between these eminent lawgivers sufficient to convince impartial and candid inquirers. Banier allows, that some confused knowledge of the laws of Moses furnished Minos with a model for those of Crete.

Minos, after having governed his subjects with a mild and gentle sway, died in Crete, and being interred there, had this epitaph inscribed upon his tomb, ΜΙΝΟΣ ΤΟΥ ΔΙΟΣ ΤΑΦΟΣ; Minos F. Jovis Sepulchrum; when in process of time the name of Minos was defaced, and there remained only the two last words of the epitaph, the Cretans gave out that this was the tomb of Jupiter. This inscription, it is said, was defaced by the malice of the Cretans, who boasted of possessing the tomb of the father of the gods, whom they pretended to have brought up in his infancy. Accordingly, Callimachus, in a hymn addressed to Jupiter, sharply reproaches them on this account; for he says thus to the following purpose: "The Cretans are always liars, since they vaunt that they have thy tomb, O great king, who livest for ever!" To this passage the apostle alludes, when he upbraids the same people in the words of Callimachus, with the vice of lying.

MINOTAUR, MINOTAURUS, in *Antiquity*, a fabulous monster, much talked of by the poets; feigned to be half man and half bull.

The minotaur was brought forth by Pasiphae, wife of Minos II., king of Crete. It was shut up in the labyrinth of that island; and at last was killed by Theseus.

The fable of the minotaur was invented by the Greeks to make Minos odious. The occasion was this. Minos, having laid siege to Athens, reduced the inhabitants to great distress; when, consulting an oracle, they were directed to supplicate peace of Minos, the king of Crete. This he granted to them on condition that every ninth year, according to Plutarch and Ovid, or every seventh year, according to Diodorus Siculus and Apollodorus, the Athenians should send to him seven youths, and as many virgins. This article being agreed to, Minos raised the siege and withdrew to Crete, carrying with him those who were chosen by lot to be the first victims to the preservation of their country. Hence the fable originates. The Greeks said, that the king of Crete condemned the Athenian youths, who were sent to him, to fight in the labyrinth which Dædalus had built, with the minotaur, that was the offspring of the infamous passion of Pasiphae, his queen, for a white bull which Neptune had produced from the sea; that Dædalus, who was obliged to leave Athens, and remove to Crete, had favoured that monstrous passion of the queen; that from the conjunction sprung the minotaur. It was, without doubt, the hatred of the Greeks against Minos that made them invent this fable; for Plato says, that

that the favourable character which Homer and Hesiod had given of this great prince was of no avail against the malice of his enemies; and Plutarch adds, that it is dangerous to provoke a knowing people, who have it always in their power to take revenge. Servius gives us the following explication of this fable. He says, that a secretary of king Minos, named Taurus, *bull*, had an intrigue with the queen Pasiphae, in the chamber of Dædalus; and that she was at length delivered of twins, one of which resembled Minos, and the other Taurus. This occasioned the production to be reputed monstrous.

In order to account for that part of the fable, that ascribes the destruction of the minotaur to Theseus, we observe, that this young hero, having obtained his father's permission, prepared with the other youths, who had cast lots, to set out for Crete. After the performance of certain rites, Theseus set sail, and with a favourable wind speedily arrived at Crete. His fine address attracted the notice of Ariadne, Minos's daughter (see the article ARIADNE), who gave him a clue, which he happily made use of to find his way out of the labyrinth, after vanquishing the minotaur: that is, Ariadne taught her lover to vanquish Taurus, furnishing him with arms; and by the clue we may understand the draught and plan of the labyrinth which the princess gave him, and of which he made use to find his way thence after the encounter. Some indeed have said, that Theseus encountered Taurus, not in the labyrinth, but in a public place; and that this young hero, animated by the presence of the fair Ariadne, defeated Taurus, an event which gave great joy to all, even to Minos himself, who thus got rid of a formidable rival. Our author says, that the son of Pasiphae and Taurus making great desolation in the mountains to which Minos had confined him, this prince sent all the Athenian slaves to combat with him; and Theseus having gone thither in his turn, put him to death with the sword which his mistress Ariadne had given him.

MINOVERY, formed of the French *main-œuvre, q. d. handy-work*, a trespass committed in the forest, by something that is a man's handy-work; as an engine to catch deer, &c.

MINOW, or MINIM, in *Ichthyology*, a name given by the English to the small fish, called by authors the phoxinus. See CYPRINUS *Phoxinus*.

MINROW, in *Geography*, a town of Hindoostan, in the Dooab; 50 miles W. of Paltiary.

MINSFELDEN, or MUNZFULDEN, a town of Germany, with a citadel; 25 miles E. of Coblentz.

MINSK, a town of Russian Lithuania, and capital of a palatinate of the same name, situated on the Swislocz; 250 miles N.E. of Warsaw. N. lat. 53° 43′. E. long. 27° 40′.

MINSTER, a town of Lower Bavaria; seven miles N.E. of Brannau.

MINSTER, Saxon, *Mynster*, or *Mynstre*, anciently signified the church of a monastery or convent.

MINSTREL, an ancient term for a fiddler, or player on any other kind of musical instrument.

Borel derives the word from *manus* and *histrio*, one who diverts with the hand; or from *minor histrio, little buffoon*: Du-Cange from *ministellus*, a diminutive of *minister*, because the minstrels were anciently ranked among the lower officers, ministers, or servants.

According to Dr. Percy, in his Essay on the Ancient English Minstrels, the word is derived from the French *menestrier*; and was not in use here before the Norman conquest: and it is remarkable, that our old monkish historians do not use the words *citharoedus*, *cantator*, or the like, to express a minstrel in Latin; but either *mimus*, *histrio*, *joculator*, or some other word that implies gesture. Hence it should seem that the minstrels set off their singing by mimickry or action; or, according to Dr. Brown's hypothesis, united the powers of melody, poem, and dance. These minstrels were probably the genuine successors of the ancient bards, who joined the arts of poetry and music, and sung verses to the harp of their own composing. After the conversion of the Saxons to Christianity, the poets and minstrels became two separate professions: and the latter continued to be a distinct order of men, and got their livelihood by singing verses to the harp at the houses of the great: where they were hospitably and respectfully received, retaining many of the honours shewn to their predecessors, the Bards and Scalds. And though some of them only recited the compositions of others, many of them still composed songs themselves, and all of them could probably invent a few stanzas on occasion.

Mr. Ritson, in his Introduction to "Ancient English Metrical Romances," blends the English minstrels with the jugglers, whose tricks of legerdemain formed another branch of the amusement of our ancestors. Although it be allowed, that the same person might occasionally practise both arts, yet we see no reason for doubting, that they were separate and distinct professions; nor can we admit the supposition of Mr. Ritson, that the minstrels, whose profession was music and the recitation of poetry, were not frequently themselves poets. Their daily bread depended upon their stock of tales and songs; and it must have been as natural for them to have composed the romances which they sung, as for a modern musician to compose the pieces which he performs. Above all, we cannot see why the arts of composition, which are admitted to have been exercised by the minstrels of France, should be supposed unattainable by those of England. Subsequent to the reign of Edward III., most of the popular French romances were translated into English, which then became the language, as well of the nobles as of the vulgar. Why the minstrels, who were most interested in these translations, should be deemed unequal to the task of accomplishing them, we can see no good reason for believing. As a wandering and idle race of men, attendant on the barons who went to war in France, they had time to acquire both languages; and the art of rhyming must have been easy to persons who almost every day of their lives were employed in poetical recitation. Minstrels and bards are often employed as synonimous terms, although the poetic powers of the bards are indisputable. As late as the reign of queen Elizabeth, this combination occurs in the poem of a Scottish satirist describing London.

"Bot yet the menstrallis and the bairdis,
Thair trowand to obtain rewardis,
About his ludgene loudlie played."

Legend of the bischop of St. Androis.

A proof how far the task of the poet and of the reciter were required from the minstrel, occurs in a very ancient poem, of which there is one MS. in the British Museum, and another in the library of Peterborough cathedral. It contains the history of an intrigue betwixt Thomas of Erceldoune, called the Rhymer, and the queen of fairies, by whom, as every one knows, he was transported to the the "Lond of Faerie," and gifted with those supernatural powers of poetry and prophesy, by which he was afterwards distinguished. The following dialogue passes betwixt

twixt the bard and his faery leman upon this memorable occasion.

> " Fare wel. Thomas, I wend my way,
> I may no longer ftande with the.—
> Gif me fum tokyn, lady gaye,
> That I may fay I fpake with the.—
>
> To harp and carpe, Thomas, wher fo ever ze gon,
> Thomas, take the thefe with the.—
> Harping, he faid, ken I non,
> For tong is chefe of mynftralcie.—
>
> If thu wil fpelle, or talys telle,
> Thomas thu fhal never make lye ;
> Wher fo ever thu goo, to fryth or felle,
> I pray thu fpeke never non ille of me."

From this decifive declaration, which a poet and minftrel made on the nature of his own profeflion, it appears plainly, that, in more ancient times, the minftrel's principal and moft honourable occupation referred to poetry, rather than mufic; and the Rhymer might have been juftly defcribed as one "who united the arts of poetry and mufic, and fung verfes to the harp, of his own compofing," if he had not difdained the mufical fkill to which it was Mr. Ritfon's perfuafion that the talents of the minftrel were exclufively limited. See Edinb. Rev. No. XIV. p. 394, &c.

Mr. Ellis, in the Introduction to his " Specimens of early Englifh Metrical Romances," has given us a plain and comprehenfive view of the rife and progrefs of the minftrels and their poetry. Of his account we fhall avail ourfelves in the compilation of this article.

Normandy appears to have been the cradle of minftrelfy. The Northmen who wrefted that province from the feeble fucceffors of Charlemagne, had, doubtlefs, like all other barbarous people, efpecially the Scandinavian tribes, their national poets, under the name of fcalds, or by whatever other term they were diftinguifhed. On their fettling in Neuftria, their native fpeech fpeedily melted down into the more commodious and extended language ufed by the inhabitants of Northern France, which was called *romance*, being, in fact, a corrupted Latin, introduced by the Romans into their Gallic province. In this language, the minftrels compofed moft of their works, until, from that circumftance, the word romance, from fignifying the early Norman-French, came at length to mean thofe chivalrous tales ufually compofed in that tongue.

" It appears likely," fays Mr. Ellis, " that they were carried by Rollo into France, where they probably introduced a certain number of their native traditions; thofe, for inftance, relating to Ogier le Dancis, and other northern heroes, who were afterwards enlifted into the tales of chivalry; but that, being deprived of the mythology of their original religion, and cramped, perhaps, as well by the fober fpirit of Chriftianity, as by the imperfection of a language whofe tamenefs was utterly inapplicable to the fublime obfcurity of their native poetry, they were obliged to adopt various modes of amufing, and to unite the talents of the mimic and the juggler, as a compenfation for the defects of the mufician and poet. Their mufical fkill, however, if we may judge from the number of their inftruments, of which very formidable catalogues are to be found in every defcription of a royal feftival, may not have been contemptible; and their poetry, even though confined to fhort compofitions, was not likely to be void of intereft to their hearers, while employed on the topics of flattery or fatire. Their rewards were certainly, in fome cafes, enormous, and prove the efteem in which they were held; though this may be partly afcribed to the general thirft after amufement, and the difficulty experienced by the great in diffipating the tedioufnefs of life; fo that the gift of three parifhes of Gloucefterfhire, affigned by William the Conqueror for the fupport of his *joculator*, may, perhaps, be a lefs accurate meafure of the minftrel's accomplifhments, than of the monarch's power and of the infipidity of his court.

" To the talents already enumerated, the minftrels added, foon after the birth of French literature, the important occupation of the *difeur*, or *declaimer*. Perhaps, the declamation of metrical compofitions might have required, during their firft ftate of imperfection, fome kind of chant, and even the affiftance of fome mufical inftruments, to fupply the deficiencies of the meafure; perhaps, the aids of gefture and pantomime may have been neceffary to relieve the monotony of a long recitation: but at all events it is evident, that an author who wrote for the public at large, during the eleventh, twelfth, and thirteenth centuries, was not lefs dependent for his fuccefs on the minftrels, than a modern writer of tragedy or comedy on the players of the prefent day. A copyift might multiply manufcripts for the fupply of convent-libraries; but while ecclefiaftics alone were able to read, there was no accefs to the ears of a military nobility, without the intervention of a body of men who travelled in every direction, and were every where welcomed as the promoters of mirth and conviviality.

" The next ftep was eafy. Being compelled to a frequent exercife of their talent in extemporaneous compofitions, the minftrels were probably, like the *improvifatori* of Italy, at leaft equal, if not fuperior, to more learned writers, in the merely mechanical parts of poetry; they were alfo better judges of the public tafte. By the progrefs of tranflation they became the depofitaries of nearly all the knowledge of the age, which was committed to their memory: it was natural, therefore, that they fhould form a variety of new combinations from the numerous materials in their poffeffion; and it will be fhewn hereafter, that many of our moft popular romances were moft probably brought by their efforts to the ftate in which we now fee them. This was the moft fplendid era of their hiftory, and feems to have comprehended the latter part of the twelfth, and perhaps the whole of the thirteenth century. After that time, from the general progrefs of inftruction, the number of readers began to increafe; and the metrical romances were infenfibly fupplanted by romances in profe, whofe monotony neither required nor could derive much affiftance from the art of declamation. The vifits of the minftrels had been only periodical, and generally confined to the great feftivals of the year; but the refources, fuch as they were, of the ponderous profe legend were always acceffible. Thus began the decline of a body of men, whofe complete degradation feems to have been the fubfequent refult of their own vices. During the period of their fuccefs they had moft impudently abufed the credulity of the public; but it is a whimfical fact, that the fame fables which were difcredited while in verfe, were again, on their transfufion into profe, received without fufpicion. It fhould feem that falfhood is generally fafe from detection, when concealed under a fufficient cloak of dulnefs."

This hiftory folves a difficulty which Mr. Ritfon, already cited, found in reconciling the degraded ftate of the minftrels to the high rewards and countenance which they fometimes received, even in preference to thofe of the clerical profeffion. It appears, on one occafion, that two mendicant friars foliciting hofpitality at the gate of a convent, were received with acclamation under the idea of their being minftrels, and kicked out again when they announced their real character. It is alſo proved, we believe, that one minſtrel received four ſhillings for his performance, and ſix prieſts only ſixpence, at the ſame feſtival. But ſuch inſtances of extravagant reward to individuals of a claſs which dedicates perſonal exertions to public amuſement, are conſiſtent with the general diſreſpect to which this body in general is condemned.

There are two remarkable facts in hiſtory, which prove that the profeſſion of a minſtrel was held in great reverence among the Saxon tribes, as well as among their Daniſh brethren. In the year 878, when king Alfred wiſhed to learn the true ſituation of the Daniſh army, which had invaded his realm, he aſſumed the dreſs and character of a minſtrel, *fingens ſe joculatorem, aſſumpta cithara*, &c. and under this character, though he could not but be known to be a Saxon, obtained an honourable reception. About ſixty years after, a Daniſh king made uſe of the ſame diſguiſe to explore the camp of our king Athelſtan. The minſtrel was, therefore, a privileged character with both theſe people: and ſo late as the reign of Edward II. the minſtrels were eaſily admitted into the royal preſence; an inſtance of which is mentioned by Stow (Survey of Lond. 1703, p. 469.) In the fourth year of Richard II. John of Gaunt erected at Tutbury, in Staffordſhire, a court of minſtrels, with full power to receive ſuit and ſervice from the men of this profeſſion within five neighbouring counties, to enact laws and determine their controverſies, &c. for which they had a charter. See Plott's Hiſt. Staff. p. 435, &c.

The minſtrels continued down to the reign of Elizabeth; in whoſe time, however, they had loſt much of their dignity, and were ſinking into contempt and neglect; yet ſtill they ſuſtained a character far ſuperior to any thing we can conceive at preſent of old ballads. Towards the end of the ſixteenth century this claſs of men loſt all credit, and were ſunk ſo low in the public opinion, that in the thirty-ninth year of Elizabeth, a ſtatute was paſſed by which minſtrels, wandering abroad, were included among rogues, vagabonds, and ſturdy beggars, and were adjudged to be puniſhed as ſuch. This act ſeems to have put an end to the profeſſion, for after this time they are no longer mentioned. Judge Blackſtone obſerves, that in ſome manors, the copyholders were bound to perform many ſervile offices for the lord, who found them meat and drink, and ſometimes (as is ſtill the uſe in the Highlands of Scotland) a minſtrel or piper for their diverſion. Comm. b. ii.

The firſt compoſitions of the minſtrels, according to Mr. Ellis (ubi ſupra), ſeem to have been unadorned annals or hiſtories, reduced to meaſure for the convenience of the reciter, who was to retain them upon his memory. This field, however, ſoon became too barren and unintereſting. Other ſources of narration were ſought for. Some occurred in the ancient ſongs of the ſcalds, the legitimate productions of the minſtrels. Others of Arabian origin found their way to France through Spain. But a much more numerous claſs was derived from the tales of the Armoricans, the neighbours of the Normans, who derived themſelves from a Welſh colony. From this ſource, the minſtrels probably drew their firſt accounts of

> "——————— What reſounds
> In fable or romance, of Uther's ſon,
> Begirt with Britiſh and Armoric knights."

This theme, however, acquired its chief popularity after the acquiſition of England by William the Conqueror. It is now completely proved, that the earlieſt and beſt French romances were compoſed for the meridian of the Engliſh court, where that language continued to be excluſively uſed, at leaſt till the time of Edward III. When the Norman race of monarchs had once ſecured themſelves on the throne of England, and identified the honour of that country with their own, they began to feel an intereſt in its early hiſtory, and to liſten with applauſe to the feats of its heroes. The legends of the Welſh, on theſe occaſions, were much more acceptable than thoſe of the Saxons. The latter were the people whom the Normans had conquered, and whoſe kings they had diſpoſſeſſed: the praiſe, therefore, of their departed heroes revived ſentiments of diſcord, better forgotten by all parties. But the exploits of the Britiſh were carried back to ſo ancient a period, and ſo intermingled with Celtic fable, that they recalled no ſentiments of ancient independence, and ſuggeſted no ideas dangerous to the Norman race. The exploits of Arthur were therefore unanimouſly adopted as the ſubject of tales and romances without end; and theſe were drawn by the Norman minſtrels from the Britiſh traditions flowing from Wales, and floating in what had lately been the Britiſh kingdom of Cumberland; but eſpecially from the works of Geoffrey of Monmouth.

Mr. Ellis ſhews, that the ſtate of Wales, during the eleventh, twelfth, and thirteenth centuries, was favourable to an exchange of literary materials betwixt the bards of that country and the Norman minſtrels, as well as between the former and their brethren of Armorica.

But as there is reaſon to believe that the Britiſh lays were ſeldom if ever committed to writing, it might be expected that different minſtrels would tell the ſame ſtory with ſome variations; that, unable to retain in their memory the whole of a long narrative, they would carry off, in the firſt inſtance, detached adventures, which they would afterwards connect as well as they were able; and that a ſyſtem of traditional hiſtory, thus imperfectly preſerved through the medium of a very looſe tranſlation, and already involved in much geographical and chronological confuſion, would aſſume the fabulous appearance which we find in the French narratives called romances. See Romance.

MINT, the place in which the king's money is coined. Anciently there were mints in almoſt every county in England; but as it is one of the prerogatives of the king to coin the money of the realm, the buſineſs of coining was carried on principally in the Tower of London, from the time of William the Conqueror to the year 1811. At this latter period a very elegant building was completed on the eaſtern ſide of Tower-hill, in which the coinage is now performed with a ſimplicity, diſpatch, and accuracy that can ſcarcely be conceived by any who have not been witneſſes of the ſeveral operations.

Coining metallic money was originally performed by the hammer, and afterwards by what was called the ſcrew-preſs, or mill and ſcrew. Theſe operations have been amply deſcribed under the word Coinage, to which we beg to refer our readers. In this place we ſhall endeavour, in very few words, to conduct them through the ſeveral offices of the New Mint, and deſcribe, as well as we can, the buſineſs and proceſſes carried on in each.

Almoſt all the money, now coined in this kingdom, is from bullion received from the Bank of England; from which it is ſent to the "maſter of the mint's aſſay-office:" here it is received into what is called the ſtrong-hold, and there kept till its fineneſs is aſcertained, in order that its true value may be computed.

This being aſcertained, the parties concerned are deſired to attend at the office of receipt and delivery to witneſs its weight, and to be informed of its fineneſs, and, conſequently, of its value; the ſtandard weight of the bullion being determined by the calculation of the reſpective offices.

A mint-

A mint-bill is now made out and given to the owner of the bullion, by which he knows the exact value of his deposit. The next thing is to deliver the bullion to the melting-house, which is furnished with a variety of apparatus, adapted, not only to the melting of the gold and silver, but the lifting in and out the pots containing the precious metals, with safety, ease, and expedition. The silver is melted in pots of cast-iron, but the gold is melted in smaller pots manufactured from black-lead, which, according to the modern chemistry, is a carburet of iron. The silver is run into plates ten inches long, seven wide, and about five-eighths of an inch thick: the gold-plates are ten inches in length, four in breadth, and three-eighths of an inch in thickness. While the metal is pouring into the moulds, there are three portions taken, from the top, the middle, and bottom of each pot, and carried to the king's assay-office, there to be examined by the master of that office, and not permitted to pass into work until the fineness of the metal is accurately determined. The furnaces used are air-furnaces, and the fuel is coke.

In the process of melting there will necessarily be waste: every thing, therefore, that can possibly contain any portion of the precious metals, such as the sweepings of the melting-house, &c. are collected and carried to another apartment, in which are erected two grinding and two triturating mills, where the sweep is worked up, and the fine metals in part recovered, in the manner practised by refiners and gold-smiths.

The sweep, thus brought together, is ground into a powder, and passed through a fine sieve, by which the larger grains of metal are obtained. The sweep is then put, in small portions, into a wooden bowl, having two iron handles, by which it is carefully washed: the lighter particles, being absorbed by the water, are collected in a large tub; the heavy or metallic ones are found deposited at the bottom of the bowl. By these means the most considerable of the particles of gold and silver are obtained. The powdered sweepings, however, which have been collected after the washing process, still contain portions of metal; to obtain these, the sweep, in certain portions, is put into a mill, containing generally about one hundred weight of mercury, the remainder of the mill being filled with water: this is commonly called the triturating mill, and each charge is agitated about four hours with an iron instrument, having four arms placed horizontally, in the shape of a cross, and fixed to the centre of the mill; and for the better agitation of the sweep and mercury, the motion of this mill can be reversed at pleasure.

From the melting-house, the plates above described, provided they are found by the assay-master to be of the exact degree of fineness, are carried to the ROLLING-*Mill*, (which see.) They are first hot-rolled, that is, made red-hot, in a furnace adapted to the purpose, and then passed through a pair of cast-iron rollers. In the room in which this operation is performed there are four pair of rollers, which (as they require an immense power) are put in motion by a steam-engine, of a power equal to that of thirty horses. The rollers are placed very near the furnaces, and the metal, being brought to what is called a blood-red heat, is taken out by a man with a pair of smith's tongs, and immediately returned by another man, and again passed through while hot two or three times, by which it is greatly extended: after this, it is annealed. See NEALING.

This process is called the breaking-down rolling, and when finished the plates of silver are about $\frac{3}{16}$ths of an inch thick. They are then cut into slips by a pair of circular shears attached to the shafts, by which the rollers are worked, after which they are finished in what are called the adjusting rollers, which are also made of cast-iron, and very finely polished. In this process the slips are rolled cold, and when a piece cut from the middle of each is found of the proper standard weight, they are carried to another apartment, called the cutting-out room, containing twelve machines worked by a steam-engine of the power of sixteen horses. With these machines the blank pieces are cut out from the strips or laminæ just mentioned with great ease and velocity. The only manual labour required, is that performed by a boy nine or ten years old at each machine; he quickly learns the art of presenting the laminæ to the cutters, which instantly cut out the blank pieces of metal; these so struck fall through a hole that conducts to a box placed below to receive them. Each machine will cut 60 pieces in a minute, of course the twelve will produce 720 in a minute, or 43,200 in an hour. Formerly these machines were worked by hand by a man or boy at each cutter, but no manual labour can operate so accurately and well as the power obtained by the steam-engine. The instruments with which the blanks are cut (called a bed and punch), are made of steel, of the exact diameter of the piece of money required.

From this apartment the blanks are carried to the adjusting-room, where every piece is most accurately weighed, the gold twice, at least, and the silver once: those pieces that are found too heavy are reduced by the file, called a float, and those that are found too light, which occasionally occurs, are re-melted.

The blanks, now properly adjusted, are carried to the milling-room. Into this, the writer of the present article was not allowed to enter; the process of milling being a secret by the very constitution of the mint. This has always been the case since the time of Peter Blondeau, who introduced the milling in 1662, as appears from an extract from Mr. Folkes, in his "Tables of English Silver Coins," in which he observes, and the observation holds good even now, though at the distance of sixty-five years; that "it may be noted that this practice of keeping secret the manner of edging the money, is still observed in our mint, all those who are entrusted with it being sworn not to discover it: notwithstanding, the manner in which the same operation is performed in several foreign mints, is there publicly shewn."

The blanks, when milled, are annealed, or softened, in order that they may be fitted to receive the impression.

The next operations are pickling and cleaning. The process of pickling is to throw the pieces of gold, thus annealed, into a strong solution of super-sulphat of alumine, those of silver into a solution of the super-sulphat of potash.

When the pieces are properly blanched, they are taken into another room to be dried and cleaned, which operation is performed by agitation in sieves, containing saw-dust, over a gentle heat.

They are now taken to what is properly called the coining-room. In this apartment there are eight coining-presses worked by a ten horse-power steam-engine; the apartment also is, in the winter months, heated with steam, so as to be kept to an uniform temperature. The machines are worked with the most perfect accuracy, and with such rapidity, that each will produce about 60 in a minute; and on the average, allowing for the necessary delays in working forty pieces of money, that is 320 guineas, &c. will pass through the eight machines in a minute, or about 19,200 in an hour. These machines require also one boy of ten or twelve years of age to each, who, by supplying the machine with the planchets, runs no risque of injury to his fingers, as the machine contains in itself a self-feeder or layer-on; the busi-

ness

nefs of the boy being only to fill the layer-on, through a tube with the blanks. From this tube, the machine places the blanks upon the dye, and when ftruck, difplaces one piece and replaces another, and fo on as long as the fteam-engine is kept at work. The coin thus completed is carried to the mint-office, where the king's affayer attends, and where the procefs called PIXING, (which fee,) takes place, to afcertain the weight and finenefs of the monies before delivery.

The two faces of the coin are ftruck at once, the upper and under dye being both engraved for the purpofe. The dyes are the workmanfhip of fome capital engraver; he, of courfe, makes the pattern upon foft fteel: from this, many others are taken at an office in the mint, and hardened, as is defcribed under the article CASE-HARDENING. The engraver is called upon to verify the accuracy of the dyes made ufe of, with the pattern or mould which he has furnifhed.

In the time of Charles II., when the Englifh coins were brought to great perfection, John Roetier, a native of Antwerp, and Thomas Simon, were engravers to the mint. They were both called upon to make models or pattern pieces of money, to be exhibited at court; his majefty is faid to have given the preference to thofe by Roetier, which were ordered to be followed in the puncheons or dyes to be made for the new money. "Which preference," fays Mr. Folkes, "fo far exafperated Simon, who did not value his performances lefs than they deferved, nor knew how to fubmit to a foreign rival; that he thereupon immediately quitted the mint, or, for fome apprehended mifbehaviour upon the occafion, was foon after removed from the office of one of the chief engravers."

It was in the year 1663, that he produced that inimitable crown, with the petition round the edge, that is now valued by the curious as a mafter-piece in this fort of workmanfhip. It refembles what were the common milled five fhilling pieces, but the king's head is larger; the face and the garment are covered with a fort of frofted work. The letters are expreffed by outlines frofted in the middle, and under the head is the name of Simon: upon the reverfe there is a centre, inftead of the ufual ftar, the figure of St. George on horfeback, encircled with the garter. The date is 1663, and upon the edge is the artift's petition, *viz.* "Thomas Simon moft humbly prays your majefty, to compare this his trial-piece with the Dutch, and if more truly drawn and emboffed, more gracefully ordered, and more accurately engraven, to relieve him." It is faid, there were not more than twenty of thefe pieces ftruck off with the petition, and a fmall number without. We have feen one of the twenty in poffeffion of the Rev. Dr. Difney, from the collection of the late Mr. J. Hollis; it is in the higheft ftate of prefervation: and in the memoirs of Mr. Hollis is a fine engraving of the medal, a little magnified. It is not afcertained what relief Simon obtained upon this petition, but it is pretty clear he was never afterwards employed in the mint

MINT, *Officers of the*, are, 1. The warden, who is the chief, and is to receive the bullion, and overfee all the other officers. This officer has under him a deputy and two clerks. 2. The mafter-worker, with three clerks; he receives the bullion from the warden, caufes it to be melted, and delivered to the moniers; and takes it from them again when coined. 3. Comptroller, with a deputy and clerk, who is to fee that the money be made to the juft affize, and to overfee the officers. 4. The affay-mafter, who weighs the filver and gold, and fees whether it be ftandard. (See REMEDY.) This officer, called the king's affay-mafter, has under him a clerk. 5. The mafter's affay-mafter, and the probationer affayer. 6. The furveyor of the melting, who is to fee the filver caft out, and that it be not altered after it is delivered to the melter, *i. e.* after the affay-mafter has made a trial of it. 7. The clerk of the irons, who is to fee that the irons be clean, and fit to work with. Thefe two offices are united in one perfon, who has a deputy and clerk. 8. The chief engraver, who engraves the dyes and ftamps for the coinage of money: there is alfo an affiftant engraver, and a probationer engraver, with a fmith, affiftant to the engravers. 9. The melters, who melt the bullion before it comes to coining. 10. The blanchers, who anneal, or boil and cleanfe the money. 11. The porter and office-keeper, who keep the gate, &c. of the mint. 12. The provoft to the company of moniers, acting as engineer, who provides for all the moniers, and overfees them. And, laftly, the company of moniers; fome of whom fhear the money, fome forge it, fome ftamp or coin it, and fome round and mill it. In this office, there are alfo the weigher and teller; receiver; king's clerk, and clerk of the paper; furveyor of the money-preffes; folicitor and affiftant; warden's deputy, mafter's deputy, comptroller's deputy, and fubordinate clerks. See COINAGE, and the preceding article.

MINT, *Roman*, has been juftly regarded as one of the moft effential ornaments and finews of the ftate. It derived great importance from the extent of the empire through which its produce was to circulate. The "Quæftor" feems at firft to have had the direction of the mint, as well as of the treafury. About the time of the firft coinage of filver in Rome, or 266 years B. C., the "Triumviri Monetales" feem to have been created; though Pomponius afcribes their firft creation to the year of Rome 463, or 289 B. C. Thefe were at firft of the fenatorial rank, until Auguftus appointed them from the equeftrian, which alteration feems to have continued. The title "Triumviri," however, remained till after Caracalla, as appears from infcriptions given us by Gruter, and by Bouterouc. Under Aurelian, it is probable there was but one mafter of the Roman mint, called the "Rationalis;" a change fufpected by Pinkerton to have taken place under Gallienus. Aurelian, having conquered the revolted provinces, and united the whole empire again, feems to have altered the form of the mints in the capital provincial cities, and to have ordered them all to ftrike money with Latin legends, and of the fame forms; for with him firft appear coins on this plan with mint-marks of cities and offices. He feems alfo to have permitted the provincial cities to ftrike gold and filver as at Rome: and we know from his coins that the "Aureus," which had diminifhed by degrees to about 80 grains, was by him reftored to 100. On this occafion, the moniers, who loft half their profits, and three-fourths of whom loft their work, caufed commotions, which terminated in a rebellion, the fuppreffion of which was attended, on the part of Aurelian, with the lofs of 7000 of his beft troops. About this time, the "Procurator Monetæ" feems to have fucceeded the "Rationalis." In the Roman colonies, the direction of the mint appears to have been committed to the "Duumviri," or two annual magiftrates, elected in imitation of the confuls at Rome. The engraving of the dye was a work of labour and of genius; and at Rome Greek artifts were ufually employed in it. The engravers of the dye were called "Cœlatores:" other officers employed in the mint were the affayers of the metal, "Spectatores," "Expectatores," or "Nummularii." The refiners were denominated "Cenarii;"

narii;" the melters "Fufarii," "Flatuarii," "Flaturarii." The "Equatores Monetarum" adjufted the weight. The "Suppoftores" put the pieces in the dye, and the "Malleatores" ftruck it. A "Primicerius" was at the head of each office; and there was a foreman, called "Optio et Exactor." Pinkerton's Eff. on Med. vol. i.

MINT was alfo a pretended place of privilege in Southwark, near the king's bench, put down by ftatute. If any perfons, within the limits of the mint, fhall obftruct any officer in the ferving of any writ or procefs, &c. or affault any perfon therein, fo as to receive any bodily hurt, the offender fhall be guilty of felony, and be tranfported to the plantations, &c. Stat. 9 Geo. I.

MINT, in *Botany*, &c. See MENTHA.

MINT, *Corymbiferous*, a name given by fome to a fpecies of tanzy.

MINT, *Cat's*, the Englifh name of a genus of plants, called by botanical writers *cataria*. See CATMINT.

MINTERS, or MONIERS. See MONEYERS and MINT.

MINTING is fometimes ufed for the coining of money.

MINTON, in *Geography*, an ifland in the Indian fea, near the W. coaft of the ifland of Sumatra, a little S. of the line. E. long. 97° 8'.

MINTURNÆ, in *Ancient Geography*, a town of Italy, in Latium, upon the Appian way, near Formiæ on the W., and Sueffa Arunca on the E. fituated on the Liris, at fome diftance from its mouth. Livy fpeaks of it as a very ancient city. The Romans gained poffeffion of it by treafon, in the year of Rome 439, and planted a colony in it. But the event which rendered it particularly memorable, was the imprifonment of Marius in this town, and his efcape, in confequence of ftriking terror into the mind of the foldier who was fent to affaffinate him. See MARIUS.

MINUARTIA, in *Botany*, fo called by Lœfling in commemoration of a Spanifh botanift of the name of Minuart, an apothecary at Madrid, with whom Lœfling was acquainted while in Spain, and from whom he received many botanical obfervations, as appears by various paffages in his letters publifhed by Linnæus.—Lœfl. It. 48. Linn. Gen. 42. Schreb. 58. Willd. Sp. Pl. v. 1. 492. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 184. Juff. 300. Lamarck Illuftr. t. 52.—Clafs and order, *Triandria Trigynia*. Nat. Ord. *Caryophyllei*, Linn. and Juff.

Gen. Ch. *Cal.* Perianth inferior, erect, long, compreffed, of five, awl-fhaped, rather ftiff, permanent leaves. *Cor.* none. Nectary compofed of a few depreffed glands within the calyx. *Stam.* Filaments three, capillary, fhort, inferted into the receptacle; anthers roundifh. *Pift.* Germen fuperior, triangular; ftyles three, fhort, thread-fhaped; ftigmas thickifh. *Peric.* Capfule oblong, triangular, a little fhorter than the calyx, of one cell and three valves. *Seeds* not numerous, roundifh, compreffed.

Obf. *Minuartia montana* is faid occafionally to be found with traces of five minute petals, which are poffibly what Lœfling defcribed as nectariferous glands.

Eff. Ch. Calyx of five leaves. Corolla none. Capfule with one cell and three valves. Seeds few.

1. M. *dichotoma*. Linn. Sp. Pl. 132. Lœfl. It. t. 1. f. 3.—Leaves briftle-fhaped. Stem fimple, erect. Flowers feffile, crowded together in a forked manner.—Very plentiful on the hills about Madrid.—This little annual fcarcely exceeds an inch in height. The *ftem* is fimple, erect, rarely branched, dichotomous at the upper part. *Leaves* oppofite, awl or briftle-fhaped, erect, fo clofe as to cover the whole ftem. *Flowers* feffile, cymofe, forming a little fquare head, clofely forked. *Bracteas* long, awl-fhaped, rigid, twice or thrice as long as the flower. *Seeds* from five to eight, kidney-fhaped. The whole plant affumes a brownifh-herbaceous colour.

2. M. *montana*. Linn. Sp. Pl. 132. Lœfl. It. t. 1. f. 4. —Flowers crowded, lateral, alternate, fhorter than the bractea.—Found in wet fandy fituations on the fides of hills about Madrid.—*Root* annual, fibrous, very fmall. *Stem* fimple, fcarcely an inch in height, jointed, fmooth. *Leaves* oppofite erect, briftle-fhaped, broader at the bafe, ftriated, acute, rigid. *Flowers* feffile, about three together, rarely folitary. *Seeds* from three to feven, fmall.

3. M. *campeftris*. Linn. Sp. Pl. 132. Lœfl. It. 122.— Flowers crowded, terminal, alternate, fhorter than the bractea.—Found in fituations fimilar to the two laft fpecies. —*Root* annual, very flender and fimple, fomewhat twifted. *Stem* quite fimple, and very fhort, covered with leaves, round. *Leaves* oppofite, flat, awl-fhaped, ftriated, rigid, clofe to the ftem, numerous. *Flowers* terminal, forming a compact little head, partially forked, but not univerfally fo, and in this refpect the plant chiefly differs from *M. dichotoma*. *Seeds* five or fix, compreffed, kidney-fhaped.—The whole plant has a fcaly or hufky afpect.

MINUCCIO D'AREZZO, in *Biography*, according to Boccaccio, an exquifite finger and player on the viol, in great favour with Peter of Roan, king of Sicily.

MINUET, or MENUET, in *Mufic*, a compofition anfwering to a kind of dance of the fame name, faid to be invented at Poictou; the motion of which is triple, with three crotchets in a bar $\frac{3}{4}$, though it is commonly performed in the time $\frac{3}{8}$. It has commonly two ftrains, each played twice over; the firft has four or eight bars, the laft note of which fhould be either the dominant or mediant of the mode, never the final; and the fecond has eight bars, it ufually ends on the final of the mode, with a pointed minim or whole bar.

The word is faid to be derived from the French *menu*, *little*, and fignifying a fmall pace.

It feems as if the air and dance of that name, in fuch high favour and ufe during the laft century in all the courts of Europe, as well as that of France, whence it was adopted, was either unknown to Broffard, or its character muft have been very much changed fince his time. In his Dict. de Muf. he defines *minuetto*, or *menuet*, *Danfe fort gaye*, a very lively dance. But fo far from lively and gay was this dance, that its characteriftics were grace and gravity. It has been even faid to be the only grave dance fince the difufe of the louvre, fit for perfons of high rank and dignity to dance alone at courts or great balls. But as the country-dance, at the latter end of the laft century, was fupplanted by the cotillon, the cotillon by the waltz, the inftrumental minuet by the jig, the dance itfelf of the flow minuet is wholly abolifhed. For a further account, fee MENUET.

MINUETTO *per Ballo*, Ital. a dancing minuet.

MINURI, in *Geography*, a town of Naples, in Principato Citra; 9 miles S.W. of Salerno.

MINUS, in *Algebra*. See CHARACTERS, in *Arithmetic*.

MINUS *Quo*, in *Law*. See QUO *Minus*.

MINUSCULÆ, in *Printing*, denote the fmall and running letters; as contradiftinguifhed from *majufculæ*, or capitals.

MINUTE, from the Latin *minutus*, *fmall*, in *Geography* and *Aftronomy*, is the fixtieth part of a degree.

In which fenfe minute is alfo called *prime*, or *prime-minute*.

The divifions of degrees are fractions, whofe denominators increafe in a fexagecupal ratio; that is, a minute or prime is $= \frac{1}{60}$th; a fecond, or fecond minute, $= \frac{1}{3600}$dth, &c.

In

In astronomical tables, &c. minutes are expressed by acute accents, thus, ′; the seconds by two, ″; the thirds by three, ‴.

Minute, in *Computation of Time*, is used for the sixtieth part of an hour.

Minute, in *Architecture*, usually denotes the sixtieth, sometimes only the thirtieth, part or division, of a module.

Minute is also used to signify a short memoir, or sketch of any thing hastily taken in writing.

In this sense we say, the minutes of the proceedings of the house of lords, &c.

Minutes *of Emersion*. See Emersion.

Minutes, *Meridional*. See Meridional.

Minute *Tithes*, *Minores Decimæ*, small tithes of wool, lambs, pigs, butter, cheese, &c. See Tithe.

MINUTIUS, Felix, Marcus, in *Biography*, an able apologist for Christianity in the third century, probably a native of Africa, who flourished towards the close of the reign of the emperor Septimius Severus, or about the year 210. He was educated to the profession of the law, and became an eminent pleader at Rome; where he renounced the heathen religion, and embraced that of Christ. He was author of an excellent defence of Christianity, entitled "Octavius," written in the form of a dialogue, between a heathen and a Christian, in which Minutius himself sits as judge and moderator. By this contrivance, he replies to the objections and arguments brought forward by the adversary, and refutes the calumnies cast upon Christians by the heathen philosophers, and at the same time exposes the absurdities of their creed and worship, powerfully demonstrating the reasonableness and excellence of the Christian religion. This work was, for a considerable time, attributed to Arnobius; but in the year 1560, Francis Baldwin, a learned lawyer, published it at Heidelberg, and made the discovery, in a preliminary dissertation, that Minutius was its true author. It has, since that time, gone through many editions, of which the best is that printed at Cambridge in 1712, with the dissertation of Baldwin prefixed, and "Commodiani Instructiones adversus Gentium Deos," added in the way of appendix. Gen. Biog. Lardner.

MINUZIANO, Alessandro, a learned printer in the 15th century, was born at St. Severo, in Puglia. After studying under George Merula at Milan, he succeeded him as professor of rhetoric, and held that chair, with the professorship of history, several years. He interested himself very much in the editing of the learned works that issued from his press, and at length established a printing-press of his own. The first specimen that he gave was a fine edition of all Cicero's works, in four vols. folio. After this, he published editions of various authors, ancient and modern, to many of which he prefixed learned prefaces, written in an elegant style. He was a diligent collator of old manuscripts, and took vast pains to establish the most authenticated readings. He was not free from the unfair practice, at that period but too common among printers, of pirating each other's works: and when Leo X. caused the "Annales" of Tacitus to be printed for the first time at Rome, he found means, by bribing some of the workmen employed upon it, to obtain the sheets as they were worked, and brought out a rival edition. On account of this he incurred the pope's displeasure, and involved himself in troubles from which he was scarcely able to extricate himself.

MINX, in *Zoology*, is the name of an animal in North America, very much resembling the otter. See Mustela *Vison*.

MINYA, in *Ancient Geography*, a town of Greece, in Thessaly, called also "Almonia."—Also, a town of Asia, in Phrygia.—Also, a town of the island Amorgos, situated in the most western part of the island.

MINYÆ, Minyans, an ancient people of Greece, who were dispersed through different countries. The most ancient people of this name were settled in Bœotia, and the inhabitants of Orchomené are said to have derived it from Minyas, one of their kings. Some of these Minyans conducted a colony to Iolcos, and hence the Argonauts have been sometimes denominated Minyans. Others of them joined themselves to a colony which the sons of Codrus conducted to Ionia; and they established themselves, under the direction of Athamas, at Theos, a town situated to the south of the isthmus which connects the peninsula with the continent, W. of Smyrna. Others of them, tracing their derivation from the Argonauts, settled in the isle of Lemnos, whence they were driven by the Pelasgians. These fugitives sailed to Laconia, and having encamped on mount Taygetus, the Lacedæmonians gave them land, and they intermarried with the Lacedæmonians. Of these Minyans, some in process of time aspired to the government, and rebelled against the powers that enforced the existing laws; and they were arrested, thrown into prison, and threatened with death. But their wives, having obtained permission to visit them in prison at the time when they were to be executed, changed clothes with them, and thus afforded them the means of rescue. They then retired to mount Taygetus, where they must have perished, if Theras, of the race of Cadmus, had not obtained their pardon.

MIOGA, in *Botany*, the Japanese name of a plant of the natural order of *Scitamineæ*, called by Kæmpfer *Dsjooka*, vulgarly *Mjoga*, *Mionga*, or *Megga*, Amœn. Exot. 826. (Amomum Mioga; Thunb. Jap. 14. Kæmpf. Ic. t. 1. Willd. Sp. Pl. v. 1. 7. Zingiber Mioga; Roscoe Tr. of Linn. Soc. v. 8. 348.)—Kæmpfer describes it as "one of the eatable kinds of Ginger, of a mild taste, with a reedy stem and leaves, resembling those of wild Ginger (*Zingiber Zerumbet* of Roscoe). Its flowering bulb grows from the root near the stem, at the surface of the ground. The flowers are produced in succession, each proceeding from between scales, hooded, two inches long, of a pale colour, resembling the flowers of Ginger, with a faint smell of *Petasites*, or Butter-bur."

This curious plant was sent to Kew garden in 1796, by the right hon. sir Joseph Banks, but has not yet flowered. By Kæmpfer's plate the flower-stalk appears remarkably short for a *Zingiber*, and more resembling a true *Amomum*, but there is no essential difference. The coincidences between the characters of the flowers, and the qualities of the roots, in these several species, confirm the solidity of Mr. Roscoe's arrangement, which is one of the happiest efforts that have been made in scientific botany. See Scitamineæ.

MIOKECK, in *Geography*, a town of Sweden, in West Gothland; 36 miles S.E. of Gotheborg.

MIOLENS, a town of France, in the department of Mont Blanc, at the conflux of the Arche and Isere; 10 miles E. of Chambery.—Also, a town and fortress of France, in the department of the Lower Alps; 9 miles W. of Barcelonetta.

MIOLLON, a small island on the W. side of the gulf of Bothnia. N. lat. 63° 4′. E. long. 18° 20′.

MIONIKIALLE, a town of Persia, in the province of Mazanderan; 42 miles S. of Fehrabat.

MIOSS, a lake of Norway, in the government of Aggerhuus, about 50 miles long from N. to S., and from 2 to 16 broad, containing one island, 8 miles in circuit: the southern extremity is 30 miles N.E. of Christiania.

MIOUTOLON, a fmall ifland in the Indian fea, near the coaft of Africa.

MIPARTY, *Chamber of.* See CHAMBER.

MIPROVETZ, in *Geography*, a town of Bulgaria, the fee of a Greek archbifhop ; 52 miles N.W. of Sophia.

MIQUELETS, a kind of foot foldiers, inhabiting the Pyrenean mountains : armed with piftols under their belts, a carbine, and a dagger. The miquelets are dangerous people for travellers to meet.

MIQUELON, in *Geography*, a fmall ifland in the Atlantic ocean, eight miles S.W. of Cape May, in Newfoundland. It is not more than three-fourths of a league in length, and its foil is indifferent. It was ceded to the French by the peace of Paris in 1763. The English deftroyed the fettlement in 1778, and kept the ifland till the year 1783, when it was reftored by the peace ; and in 1793 it was retaken by the Englifh, and reftored at the peace of Amiens. N. lat. 46° 56'. W. long. 56° 5'.

MIR, a town of Lithuania, in the palatinate of Novogrodek ; 24 miles S.E. of Novogrodek.

MIR *Nafer*, a town of Perfia, in the province of Adirbeitzan ; 30 miles W.N.W. of Urmia.

MIRA, a town of Italy ; 10 miles E.N.E. of Padua ; eight miles W. of Venice.—Alfo, a town of Moldavia ; 44 miles S.W. of Birlat.—Alfo, a town of South America, in the province of Chocos ; 50 miles N. of Zitara.—Alfo, a town of Portugal, in the province of Beira ; 16 miles N.W. of Coimbra.—Alfo, a river of Para, which runs into the Pacific ocean, N. lat. 1° 40'.

MIRABAT, or MIRBAT, a town of Arabia, in the province of Oman ; 260 miles S.W. of Mafcat.

MIRABAUD, JOHN BAPTIST, in *Biography*, a man of letters, was defcended from a family of Provence, and born at Paris in 1675. He was intended, in early life, for the military profeffion, and was prefent at feveral battles. After this he became a member of the congregation of the Oratory, to which fociety he continued warmly attached through the remainder of his life. Having fpent many years in literary purfuits he engaged in the fervice of the houfe of Orleans, and was entrufted with the education of two young princeffes of that family. As an author he was firft known by his tranflation of Taffo's "Jerufalem Delivered." This work gave him an entrance into the French academy in the year 1726, though not without fome murmurs from original writers, who did not fcruple to fay that the patronage of the houfe of Orleans had more contributed to procure him this diftinction, than his merit as an author. He next tranflated the "Orlando Furiofo," which was alfo favourably received by the public. In 1742 he was elected perpetual fecretary of the French academy, on the acceptance of which poft, he infifted upon renouncing the right to a double fee of attendance, which his predeceffors had enjoyed. In return for this difinterefttednefs, the academy procured for him an apartment in the Louvre, and a penfion was attached to the fecretaryfhip. Having occupied the place for feveral years, he refigned it to Duclos, who, however, infifted upon Mirabaud's retaining the penfion and apartment in the Louvre, where he died, with perfect tranquillity, in 1760, at the age of 86. He was of a mild and equal temper, and a true philofopher in his conduct and fentiments. He had compofed various works on interefting topics of literature, hiftory, and philofophy ; to the "Syfteme de la Nature," publifhed in 1770, his name is prefixed, but it is now generally believed that he was not the author.

MIRABEAU, VICTOR RIQUETTI, marquis of, a French political writer, and one of the leaders of the fect of Economifts, was born of an ancient family of Provence. His firft literary work, entitled "L'Ami des Hommes," publifhed in 1755, in three volumes, contains many ufeful ideas on rural and political economy, and difplays liberal and judicious views of the great interefts of fociety. It obtained fo much public approbation and celebrity, that the name of the work became an epithet of the author, who is diftinguifhed as "Mirabeau l'ami des hommes." He afterwards wrote in favour of provincial adminiftrations, and publifhed "Théorie de l'Impôt :" all his writings are faid to breathe a fpirit of improvement and reform, which, together with his ftrictures on the financiers, was fo little agreeable to the court, that he was for a fhort time imprifoned in the Baftile. He is varioufly reprefented, according to the different notions and feelings of the perfons who have fpoken of him and his works. He died in 1790, at the commencement of the revolution, after he had fhewn an attachment to the court, while his fon was a moft diftinguifhed leader among the popular party. All his writings were publifhed collectively in eight volumes 12mo., with the exception of one, entitled "Hommes à celebrer," in two volumes 8vo., which he fent in manufcript to his friend, father Bofcovich, by whom it was printed at Baffano.

MIRABEAU, HONORE-GABRIEL RIQUETTI, count of, fon of the preceding, was born in 1749. The impetuofity of his temper led him to difdain the ordinary purfuits of youth, though it has been thought that a contempt for thefe purfuits was the principal caufe of his want of application, for when Locke on the "Human Underftanding" was put into his hands, he fat down to the perufal of it with the clofeft attention, and after making fome progrefs in it, exclaimed "This is the book I wanted." While he was ftill a ftripling he exhibited an ungovernable and daring fpirit, with a propenfity to almoft every irregularity. Between him and his father there was the moft irreconcileable difference, fo that the marquis, who has been charged by La Harpe with tyranny in his family, obtained a lettre de cachet againft his fon, then only feventeen years old, and had him clofely confined in the ifle of Rhè for two years. On his liberation he procured a commiffion in the regiment of dragoons, with which he ferved a year in Corfica. On his return to France he precipitated himfelf into every extravagance, and became involved in great difficulties. He married a young lady of family and great fortune, but his father contributed, on the occafion, nothing more than his confent to this union, and his diffipations foon brought him into new difficulties. His conduct towards his wife was brutal, and his irregularities became fo exceffive and notorious that he was feveral times imprifoned, and once, on account of his feducing a lady, the wife of the marquis de Monnier, he was committed to the caftle of Vincennes, where he was confined nearly four years. Thefe imprifonments, by checking his career of diffipation, tended to improve and ftrengthen his mind, as he found in them no employment fo interefting as laying in ftores of information and reflection, and acquiring the habit of compofition. At Vincennes he became an author, and publifhed an abridgment of French grammar, and fome licentious productions. Thefe were followed by his celebrated "Effai fur les Lettres de Cachet, et les Prifons d'Etat," in which he pleaded for the right of every citizen to perfonal liberty, until he had been deprived of it by a legal trial, with all the energy and eloquence of one who had been a fufferer under uncontrolled authority. He next commenced an action againft his father for maintenance and arrears, in which he was fuccefsful. With the affiftance of Chamfort, a man of letters of fome celebrity, he compofed a work entitled "Confiderations fur l'Ordre de Cincinnatus," the fubject of which was a projected fociety in the United States of North America, which the friends of republicanifm looked

looked upon with jealoufy. During its compofition, he frequently confulted Dr. Franklin, then at Paris. He now became a writer by profeffion, and with a view to his maintenance went to London, where he publifhed fome volumes of a work called "Le Confervateur," in which an analyfis was given of the moft valuable current publications. In London he met with very fmall encouragement, and returned to Paris, where he wrote fome tracts on public finance. In 1786 he went to Berlin, to obferve the politics of the court, and was admitted into the prefence of, and had a converfation with, Frederic the Great, who was then attacked with his laft illnefs. From his obfervations he wrote two very free and important letters of advice, or memorials, to the next king on his acceffion. He probably had fome views to employment in the new reign, but his hopes were fruftrated by his licentious character, and his open profeffion of atheifm. He chiefly occupied his time at Berlin, with laying in materials for his ftatiftical account of the Pruffian and Saxon ftates, and for his fecret and fatirical hiftory of the court of Pruffia; he became a member of the fociety of *Illuminati*, and publifhed an "Effay on the fect of Illuminées," which appearing to difclofe its fecrets, is thought to mix with them fo many abfurd fictions as to involve the whole in ridicule.

Upon the affembling of the Notables he returned to Paris, and by the freedom of fome of his remarks, in a pamphlet againft ftock-jobbing, an order was iffued for his apprehenfion, which he fortunately evaded by a temporary concealment near Liege. He did not continue long there, but on his return to the metropolis ingratiated himfelf with the minifter Brienne, by writing againft Neckar. In 1787 he vifited Berlin, and was employed, in conjunction with his friend Mauvillon, in preparing for the prefs the work entitled "Hiftoire de la Monarchie Pruffienne," which was publifhed in the following year, in four volumes 4to. and in eight of the 8vo. fize, and obtained for the author a high reputation for political and fatirical knowledge. In 1789 appeared "Hiftoire Secrete de la Cour de Berlin," in which the reigning king of Pruffia, and feveral other great perfonages in his court, were treated with fo much difrefpect, that the work was ordered, by the parliament of Paris, to be burnt by the common hangman.

The affembling of the States-General excited in Mirabeau's mind the higheft expectations, and he, without doubt, viewed the approaching troubles of the kingdom as pregnant with events, in which his abilities would lead him to take a very confpicuous part. At the time of the elections he went to Provence, with the hope of being chofen one of the deputies of the nobleffe for that province, but being rejected as not poffeffing any property in it, he opened a grocer's fhop at Aix, put on an apron, fold his wares, and rendered himfelf fo popular, that he was elected, with the greateft acclamations, a deputy of the tiers état of that city. On the meeting of the ftates, he fet up a daily paper, which he entitled "Lettres de Mirabeau à fes Commettans," which gave fuch an account of the debates as might ferve the interefts of the popular party. Some feeble attempts were made to crufh it, but without any effect, and its circulation became very extenfive. He foon diftinguifhed himfelf as the moft eloquent fpeaker, and took a leading part in thofe difputes between the different orders, which ended in the affumption of the character of "National Affembly" by the tiers-état. It was on this occafion that a declaration was iffued by the affembly, which among other fubjects obferved, that "the denomination of 'National Affembly' is the only one befitting the affembly in the actual fituation of affairs, becaufe the members compofing it are the only reprefentatives lawfully and publicly acknowledged and verified; becaufe they are fent by almoft the whole nation, and becaufe the Reprefentation being one and indivifible, none of the Deputies chofen, in whatever order or clafs, has a right to exercife his functions feparately from the prefent Affembly." On another occafion, after a royal fitting, as it was called, the deputies were ordered by the king to depart, and the order was repeated by M. de Brèzè, grand-mafter of the ceremonies. Mirabeau rofe, and addreffing Brèzè in authoritative language, bid him go and acquaint thofe who fent him, that they were affembled by the will of the people, and that nothing but the bayonet fhould feparate them. This fpeech confirmed the tiers-état in their refiftance to the royal authority, and Mirabeau followed it by propofing and carrying a decree, declaring the inviolability of the perfons of the members. About this time he attached himfelf to the duke of Orleans, but finding that prince incapable of carrying into effect any great defigns, he withdrew from his councils. The death of his father in 1790 was of no advantage to his fortune, on account of the embarraffment in which he left his affairs, yet he found means to pay off large debts, and to live in a fplendid ftyle, which was generally attributed to the donations of the duke of Orleans. His motions were fometimes of a popular kind, fometimes tending to the fupport of authority. Though apparently a friend to order, he was thought fecretly to have been the inftigator of the worft outrages committed by the mob, over whom he poffeffed a greater influence than any other individual. In the infancy of the Jacobin club he was a conftant attendant upon its meetings, but when the members feemed defirous of overfetting the whole fyftem, he deferted and oppofed them. In May 1790 he was the warm advocate for the right of peace and war as inherent in the executive power; from this period it was generally faid that he had fold himfelf to the court, and his popularity was for fome time much impaired. He had however enough of art and management to recover his influence, though he ftill treated the Jacobins with great contempt. It is imagined that he was engaged in a plan to procure the diffolution of the national affembly, and the liberty of the king, by means of an appeal to the nation, when he was attacked by a violent difeafe which proved fatal. The danger of no individual ever excited fo univerfal an alarm; all Paris, as it were, crowded round his door, with eager enquiries, and the king himfelf fent meffages to learn the ftate of his health. He died April 2d, 1791, at the age of 42. The honours paid to his memory were almoft unprecedented. All public fpectacles were fufpended till his funeral, which was attended by all the minifters and deputies, and a vaft number of other perfons, to the Pantheon, where his body was depofited by the fide of that of Defcartes. His buft was placed in the halls of moft of the municipalities of the kingdom, and funeral fervices were performed for him in feveral of the provincial capitals. Such, however, were the mutations of the public mind, that in the very next year, when republicanifm was triumphant, his bufts were deftroyed, and his remains diffipated. Befides the works already mentioned, he publifhed a variety of pamphlets. In his perfon, Mirabeau was grofs and repulfive; in his manners, paffionate and brutal. He was the moft fplendid figure in the earlier fcenes of the French revolution, but, like a meteor, he dazzled and difappeared without leaving any lafting traces of his exiftence. No man of the time was perhaps equally qualified to fhine in political warfare. Poffeffed of great eloquence, he was capable of bearing all before him in popular debate, and of a prefence of mind which no emergency could difconcert; accuftomed to lead the opinions of the public, and deriving more popularity from the boldnefs of his writings, than he loft by the diffolutenefs of his morals, he was perfectly fitted

to

to act on the tumultuary theatre of revolutionary politics. His want of principle muft exclude him from the rank of a real patriot, yet he was probably, on conviction, a friend to thofe public rights upon which all juft and enlightened government is founded. Gen. Biog. Rabaut's Hift. of the French Revolution.

MIRABEL, in *Geography*, a province of Crete or Candia, lying to the E. of that of Candia, is populous, fertile, and abounding with oil, grain, and fruit. Formerly this province fupplied feveral French veffels with oil, and thus kept up its price for the benefit of the inhabitants; but they have fince been obliged to carry it, at a great expence, to Candia, and to fell it at a low price to the Turkifh proprietors of the foap houfes eftablifhed in that town. In confequence of this reduction of price, the cultivation of olive trees, and the manufacture of oil, have declined. The road of Mirabel faces the eaft, and affords to veffels a tolerably fafe anchorage. It is fheltered and defended by two fmall iflands fituated in front. The town is greatly diminifhed fince commerce has taken another direction. Here are ftill reckoned 1500 inhabitants, moft of whom are Greeks and cultivators. South of Mirabel lies the province of "Hiera-Petra," or "Gera-Petra," which produces, like the other province, oil, grain, various fruits, honey, wax, flax, &c. but it fuffers equally with Mirabel from the prohibition, iffued by the pacha, of felling commodities any where but at Candia. Olivier.

MIRABEL, a town of France, in the department of the Lot; nine miles N. of Montauban.

MIRABELLE, a town of Naples, in the county of Molife; 14 miles S.E. of Molife.—Alfo, a town of Naples, in Principato Ultra; 10 miles S.E. of Benevento.—Alfo, a town of Sicily, in the valley of Noto; four miles N.E. of Piazza.

MIRABILE, RETE. See RETE.

MIRABILIS, in *Botany*, a name which originated with the Spaniards, who applied to the beautiful plant, which ftill bears this name, the appellation of *Marabillas del Peru*, the Wonder, or Marvel, of Peru, on account of the great diverfity of colour in its flowers, even on the fame root. At firft, as profeffor Martyn obferves, every thing that came from the new continent was thought wonderful. The French call the plant of which we are fpeaking *Belle de nuit*, becaufe the flowers expand, and fmell fweet, at night only. Indeed the botanifts of that nation feem to have taken a violent diflike to the original name, and all that belongs to it. Tournefort called this genus *Jalapa*, which is founded in error; and Juffieu *Nyctago*, derived from the French idea. The latter is unexceptionable, but fuperfluous.—Linn. Gen. 96. Schreb. 114. Willd. Sp. Pl. v. 1. 999. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 382. Stokes Mat. Med. v. 1. 311. Lamarck Illuftr. t. 105. Gærtn. t. 127. (Nyctago; Juff. 90. Jalapa; Tourn. Inft. 129. t. 50.)—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Aggregatæ*, Linn. *Nyctagines*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five erect, rather deep, unequal fegments, permanent. *Cor.* of one petal, funnel-fhaped; tube flender, long, gradually dilated upwards, its bafe permanent, hardened, invefting the feed; limb fomewhat fpreading, plaited, in five flight equal fegments. Nectary fpherical, flefhy, furrounding the germen, obfcurely five-toothed at the margin. *Stam.* Filaments five, inferted into the edge of the nectary, attached to the tube of the corolla, thread-fhaped, inclining, unequal, extending rather beyond the tube; anthers roundifh, afcending; pollen glutinous. *Pift.* Germen turbinate, fuperior, within the nectary; ftyle thread-fhaped, the length and pofition of the ftamens; ftigma globofe, rough, afcending. *Peric.* none, except the permanent hardened bafe of the corolla. *Seed* folitary, ovate, obfcurely five-fided.

Eff. Ch. Calyx inferior, five-cleft. Corolla funnel-fhaped, its bafe inflated and permanent. Nectary a gland furrounding the germen. Seed folitary, coated.

1. M. *dichotoma.* Forked Marvel of Peru. Linn. Sp. Pl. 252. (Jalapa officinarum; Mart. Decad. 1. t. 1.)—Flowers nearly feffile, axillary, folitary, erect.—Native of Mexico, from whence its feeds were brought very early to Europe. The plant is naturally perennial, having a thick oblong flefhy *root*; but if raifed on a hot-bed, it will flower and feed the fame feafon, like the ufual race of tender annuals. If kept in a green-houfe, or planted in the open air clofe to the wall of a hot-houfe, it will endure many years, and flower more abundantly throughout the fummer. The *ftem* is herbaceous, fucculent, very bufhy, forked, knotty at the joints, three feet high, round, fmooth except a narrow hairy line at the two oppofite fides. *Leaves* oppofite, ftalked, ovate, fomewhat heart-fhaped, pointed, entire, very flightly downy or hairy at the margin and ribs. *Flowers* from the forks of the ftem, on very fhort ftalks, fweet-fcented, of a fcarlet red; their tube one and a half inch long. Calyx bell-fhaped, a quarter of an inch in length.—This plant was by fome botanifts miftaken for the Jalap of the fhops, which is now known to be a *Convolvulus*, and has bloffomed this feafon, 1812, in the garden of A. B. Lambert, efq. at Boyton, Wilts; a rare occurrence in Europe, fince the plant was fent over by Houfton, 80 years ago.

2. M. *Jalapa.* Striped Marvel of Peru. Linn. Sp. Pl. 252. Curt. Mag. t. 371. (Admirabilis peruana, rubro flore; Cluf. Hift. v. 2. 89. Mirabilia peruviana, flore luteo; Ger. em. 343.)—Flowers crowded, ftalked, erect. Leaves nearly fmooth.—Native of the Eaft and Weft Indies. Very clofely related to the foregoing, except that the *calyx* is longer, and the *flowers* more crowded together, on longer *ftalks.* The *leaves* are not quite fmooth at the edges. The *corolla* varies remarkably in colour, on which account, as well as its fragrance in the evening, the plant is highly defirable. What is faid above of the treatment of *M. dichotoma,* is equally applicable to this. Some flowers are of an uniform fcarlet red, others ftriped or fpeckled with red and white, in endlefs variety, on the fame plant. On fome they are all of an uniform very delicate yellow; while other individuals bear parti-coloured red and yellow bloffoms. Moft botanifts, and among them Linnæus, have believed this to be the real officinal Jalap; a miftake to which we have already alluded. See alfo CONVOLVULUS, fp. 90, *Jalapa.*

3. M. *longiflora.* Long-flowered Marvel of Peru. Linn. Sp. Pl. 252. Stockh. Tranf. for 1755. 176. t. 6. Sm. Exot. Bot. v. 1. 43. t. 23. (Atzoyatl, Mirabili Mexicana; Hernand. Mex. 170.)—Flowers crowded, terminal, feffile, very long, flightly drooping. Leaves downy.—Native of the more cool and mountainous parts of Mexico, flowering in September. The feeds of this elegant fpecies were fent by the French aftronomers, about the middle of the laft century, from South America, to M. le Monnier at Paris, by whofe liberality they were difperfed throughout Europe. The plant has ever fince been preferved, either as a tender annual, or the roots taken up, and kept from year to year in fand, they being, like thofe of the two former, truly perennial, and very large, externally black. The *ftem* is three or four feet high, round, repeatedly forked, downy. *Leaves* oppofite, heart-fhaped, entire, foft, downy, and vifcid, fœtid when bruifed; the lower ones ftalked; the reft feffile. *Flowers* feffile, many together at the leafy top of each branch. *Calyx* very clammy and fœtid. *Corolla* four inches long,

long, with a downy green and purplifh tube; limb white, with a purple eye. *Anthers* orange. *Stigma* large, hairy, of a rich purple. *Seed* with a curioufly teffellated dark brown coat, as big as the kernel of a filbert.

The flowers are highly fcented. A few of them gathered in an evening, when they expand, without the fœtid calyx, and placed in a glafs of water, will perfume a large apartment all night. We do not however recommend them for a bedchamber, or any clofe room. Each flower lafts only one night, but there is a copious fucceffion till the clofe of autumn.

Mirabilis, in *Gardening*, furnifhes plants of the flowery perennial kind, of which the fpecies cultivated are, the common marvel of Peru (M. jalapa); the forked marvel of Peru (M. dichotoma); and the fweet-fcented marvel of Peru (M. longiflora).

The firft fort has feveral varieties in the colour of the flowers, as purple and white, and variegated purple and yellow, but which refolve themfelves into two principal varieties; as with purple and white flowers, which are variable; fome being plain purple, others plain white, but moft of them variegated with the two colours, and all found occafionally on the fame plant; and with red and yellow flowers, generally mixed, but fometimes diftinct on the fame plant; fome plants having only plain flowers, others only variegated: but the plants which are raifed from feeds of the purple and white never produce red and yellow flowers, or the contrary.

All thefe varieties are highly ornamental during the months of July, Auguft, and September, and, when the feafon continues mild, often laft till near the end of October. The flowers opening only towards the evening, while the weather continues warm, but in moderate cool weather, when the fun is obfcured, they continue open almoft the whole day, and are produced fo plentifully at the ends of the branches, that when expanded the plant feems entirely covered with them, and from fome being plain, others variegated on the fame plant, have a fine appearance.

The fecond fpecies is common in the Weft Indies, where it is termed the *Four-o'clock flower*, from the circumftance of the flowers opening at that time of the day.

Method of Culture.—In all thefe forts the propagation is effected by fowing the feed in the fpring feafon, either on a warm border or on a hot-bed; but the latter method produces the plants confiderably more early, and in the greateft perfection. When cultivated on warm fouth borders, in the places where the plants are to remain, the feed fhould be fown about the middle of April, either in patches or in fhallow drills, half an inch deep, and fix inches afunder: and when the places can be covered with hand-glaffes, or a frame and lights, or the feed be fown in pots under thofe protections, or any other occafional fhelter during the night time or in cold weather, it will greatly forward the germination of the feed, as well as the growth of the young plants afterwards. In the latter mode about June, the plants will be fit to plant out into the borders or into pots. Moift weather fhould be chofen for this purpofe, and water and occafional fhade be given till well rooted: they then readily grow, and acquire a tolerable fize; but they do not attain to a large fize, or flower fo early by a month or fix weeks as thofe forwarded in the hot-bed.

But in the latter method of raifing them, a hot-bed fhould be prepared in March, or early in April, under frame and lights, and earthed over about fix inches deep, then fowing the feed in the earth of the bed in fhallow drills half an inch deep, as directed above, or in pots of rich earth the fame depth, plunging them in the earth of the bed. The latter is the better method. The plants foon rife; when they fhould have frefh air daily, in common with the other plants of the bed, and frequent refrefhings of water; and when nearly two inches high, be planted out into another frefh hot-bed to forward them, placing them either in the earth of the bed, four or five inches afunder, or fingly in fmall pots (thirty-twos), plunging them in the bed; water and fhade fhould be immediately given till frefh rooted, continuing the care of admitting frefh air every mild day; and about the middle or latter end of May, when they have acquired a good fize and ftrength, they fhould be inured by degrees to the full air, fo as that they may be removed into it fully about the beginning of June, choofing mild cloudy moift weather, if poffible, for the bufinefs; taking up fuch as grow in the beds with balls of earth about their roots, and planting them in the borders; but thofe in the pots may he turned out with the whole ball entire, and planted in that way. Some fhould alfo be removed into large pots for moving into particular fituations. Water fhould be directly given, and occafional fhade to fuch as require it, repeating the waterings to the whole, till they have ftruck frefh root and begun to grow, when they will not require any further culture, except the occafional fupport of fticks, which is moft neceffary in the laft fort.

As the feed ripens well, it will frequently prevent the trouble of preferving the roots. But when thefe are taken out of the ground in autumn, and laid in dry fand during the winter, fecure from froft, and planted again in the fpring, they grow much larger and flower earlier than the feedling plants: or when the roots are covered in winter with tanners' bark to keep out the froft, they often remain fecure in the borders, where the foil is dry. When the roots thus taken out of the ground are planted the following fpring in large pots, and plunged into a hot-bed, under a deep frame, they may be brought forward, and raifed to the height of four or five feet, and flower much earlier in the feafon.

It fhould be noticed that in collecting the feeds, care fhould be taken not to fave any from the plants which have plain flowers; and in order to have variegated flowers, the plain flowers fhould be pulled off from thofe plants which are intended to ftand for feed. As the fecond fort is lefs hardy than the firft and third, unlefs the plants are brought forward in the fpring they feldom flower till very late, and their feeds do not ripen perfectly.

All the forts are proper for the principal borders of pleafure grounds, being very ornamental in their large branchy growth, as well as in their extenfive flowering.

Mirabilis *Aqua*. See Water.

MIRABOLANS, or Mirobalans, in *Pharmacy*. See Myrobalans.

MIRACHOW, or Mirchau, in *Geography*, a town of Pruffian Pomerelia; 12 miles W. of Dantzic.

MIRACLE, in a popular fenfe, is a *prodigy*, or an extraordinary event, that furprifes us by its novelty.

Miracle, in a more accurate and philofophical fenfe, is an effect that does not follow from any of the regular laws of nature; or which is inconfiftent with fome known law of it; or contrary to the fettled conftitution and courfe of things: accordingly all miracles prefuppofe an eftablifhed fyftem of nature, within the limits of which they operate, and with the order of which they difagree.

Spinoza denies that any power can fuperfede that of nature; or that any thing can difturb, or interrupt, the order of things; and accordingly defines a miracle to be a rare event, happening in confequence of fome laws that are unknown to us.

Divines define a miracle, an extraordinary and wonderful effect above the power of nature, wrought by God, to manifeft his power or providence; or to give credit to fome meffenger ſenger ſent from himſelf. Thus Jeſus Chriſt evinced the truth of his miſſion, and his doctrine, by miracles; and thus alſo did Moſes. But there are ſcarcely any theological writers, that preciſely agree in their definition of a miracle. Mr. Locke defines it to be a ſenſible operation, which being above the comprehenſion of the ſpectator, is, in his opinion, contrary to the courſe of nature, and taken by him to be divine. Dr. Clarke's definition of a miracle, in the theological ſenſe of the word, is this: that it is a work effected in a manner unuſual, or different from the common and regular method of Providence, by the interpoſition either of God himſelf, or of ſome intelligent agent ſuperior to man, for the proof or evidence of ſome particular doctrine, or in atteſtation to the authority of ſome particular perſon. According to Dr. Sykes, a miracle is a deſigned effect, ſenſible, unuſual in itſelf, beyond the art and power of man to do. Dr. Chandler ſays, that a miracle is an action done, or an operation viſibly performed by any being, which is really and truly above the reach, natural power, and capacity of that being who does it, of himſelf, and without the aſſiſtance of ſome ſuperior agent to perform. With this Dr. Hutcheſon's definition nearly coincides, *viz.* that it is a work far exceeding human power, yet performed by the command, or upon the volition of a man. And the ſame writer further obſerves, that though miracles may prove the ſuperintendency of a voluntary agent, and that the univerſe is not guided by neceſſity or fate; yet that mind muſt be weak and inadvertent, who needs them to confirm the belief of a wiſe and good Deity; ſince the deviation from general laws, unleſs upon very extraordinary occaſions, muſt be a preſumption of inconſtancy and weakneſs rather than of a ſteady wiſdom and power; and muſt weaken the beſt arguments we have for the ſagacity and power of the univerſal mind. Inquiry into the Original of the Ideas of Beauty, &c.

Mr. Farmer, a late ingenious and learned writer, objects to all thoſe definitions of miracles, which repreſent them as effects unuſual, above human power, and manifeſting the interpoſition of ſuperior power: becauſe, he ſays, the term unuſual does not diſtinguiſh real miracles from many things which are not miraculous, ſuch as the rare and uncommon appearances of nature: nor does the calling a miracle an effect above human power, diſtinguiſh it from all other effects equally above human power, produced by ſuperior beings, when acting within their uſual ſphere, which, for that reaſon, cannot be miraculous. Beſides, as this definition comprehends many things, which are not miraculous, and to which no perſons apply the term; ſo it excludes many things which are allowed by all to be proper miracles. For there ſeems to be a difference between effects above human power, or which argue a higher degree of power, and effects which argue a power barely different from human, and in no manner ſuperior to it. According to this definition, beaſts and birds may work miracles; for they do many things that are above the power of man. Moreover, this definition, inſtead of deſcribing miracles by the nature of the works themſelves, deſcribe them by their author, and the degree of power neceſſary to their performance. To which it may be added, that works which argue only a power more than human, can be no abſolute proofs of a divine interpoſition: and farther, the laſt part of the definition, manifeſting the interpoſition of ſuperior power, is ſuperfluous; becauſe it is only ſaying effects above human power muſt be produced by a power above it.

This writer conſiders the contrariety or conformity of the event itſelf to thoſe laws by which the world is governed in the courſe of God's general providence, as the only circumſtance which denominates and conſtitutes it a proper miracle or not: and, therefore, before we can pronounce with certainty any effect to be a true miracle, it is neceſſary (and nothing more is neceſſary than) that the common courſe of nature be in ſome degree firſt underſtood. Miracles, in this view, are not impoſſible to the power of God, nor neceſſarily repugnant to our ideas of his wiſdom and immutability. Neither do they imply any inconſiſtency in the divine conduct, or a defect or diſturbance of the laws of nature: ſo that in the general idea of miracles, conſidered as variations from the common courſe of nature, there is nothing that can furniſh a certain univerſal proof againſt their exiſtence; and there is a power ſuperior to nature, which is ever able, and which in certain circumſtances may reaſonably over-rule what was at firſt eſtabliſhed. The writer, now cited, farther maintains, that miracles are neither the effects of natural cauſes, nor of ſuperior created intelligences, acting from themſelves alone; but that they are always to be aſcribed to a divine interpoſition; *i. e.* that they are never wrought, but either immediately by God himſelf, or by ſuch other beings as he commiſſions and empowers to perform them. In proof of this propoſition, he alleges, that the ſame arguments which prove the exiſtence of ſuperior created intelligences, do much more ſtrongly conclude againſt their acting out of their proper ſphere. Farther, the ſuppoſition of the power of any created agents to work miracles of themſelves, in this lower world, is contradicted by the obſervation and experience of all ages; there being, in fact, no proper evidence of the truth of any miracles, but ſuch as may be fitly aſcribed to the Deity. Moreover, the laws of nature being ordained by God and eſſential to the order and happineſs of the world, it is impoſſible God ſhould delegate to any of his creatures a power of working miracles, by which thoſe divine eſtabliſhments may be ſuperſeded and controlled. Beſides, the aſcribing to any ſuperior beings, God excepted, and thoſe immediately commiſſioned by him, the power of working miracles, ſubverts the foundation of natural piety, and is a fruitful ſource of idolatry and ſuperſtition. It is further urged, that if miracles were performed in favour of falſe doctrines, mankind would be expoſed to frequent and unavoidable deluſion: and, if they may be performed without a divine permiſſion, and in ſupport of falſhood, they cannot be credentials of a divine miſſion, and criterions of truth. So that, upon the whole, if ſuperior beings really poſſeſs the miraculous powers which ſome writers have aſcribed to them, the exerciſe of thoſe powers, by good and evil agents, would either expoſe mankind to neceſſary and invincible error, or entirely deſtroy the credit and uſe of miracles, under the idea of criterions of truth and authentic credentials of a divine miſſion. If we appeal to the evidence of revelation, on this ſubject, we ſhall find, that the view which the ſcripture gives us of good angels, of the devil and his angels, as alſo of the ſouls of departed men, is inconſiſtent with their liberty of working miracles; and the view which the ſacred writers give us of the gods of paganiſm is alſo abſolutely inconſiſtent with their poſſeſſing a power of working miracles. Nevertheleſs, it has been much diſputed, how far it may be in the power of the devil to work miracles? or wherein the ſpecific difference lies between the miracles of Moſes, and thoſe of Pharoah's magicians? thoſe of Jeſus Chriſt and the apoſtles, and thoſe of Simon Magus and Apollonius Tyaneus? Whether the latter were any more than mere deluſions of the ſenſes; or whether any ſuper-natural and diabolical power concurred with them. See MAGICIAN; under which article it is ſhewn, that the magicians, diviners, and ſorcerers of antiquity, who pretended by the aſſiſtance of the heathen deities, &c. to foretel future events, or to work miracles, are branded in scripture as mere impostors, incapable of supporting their pretensions by any works or predictions beyond human power or skill. The scripture likewise reproaches the pretences to inspiration and miracles, made by false prophets, in support of error and idolatry, as the sole effects of human craft and imposture. And, therefore, since angels, whether good or evil, the spirits of departed men, the heathen deities, magicians, and false prophets, are the only agents, who have ever been conceived as capable of working miracles, either in opposition to God, or without an immediate commission from him; and the scripture denies to all these the power of performing any miracles; it does in effect deny, that any single miracle has ever been performed without the immediate interposition of God. It is likewise alleged, that the scriptures represent the one true God, as the sole creator and sovereign of the world, which he governs by fixed and invariable laws; that to him they appropriate all miracles, and that they urge them as demonstrations of his divinity and sole dominion over nature, in opposition to the claims of all other superior beings. The scriptures also uniformly represent all miracles, as being, in themselves, an absolute demonstration of the mission and doctrine of the prophets, at whose instance they are performed; and never direct us to regard their doctrines as a test of the miracles being the effect of divine interposition. Accordingly, the miracles of Christ, in particular, were a demonstration (not a partial and conditional, but a complete and absolute demonstration) of his mission from God: and they were farther designed to evince his peculiar character as the Messiah or anointed; *i. e.* his regal commission and power, or his right by divine designation to dominion and judicature over mankind. And it may be observed, with respect to all the miracles of the New Testament, that their divinity, considered in themselves, is always either expresly asserted, or manifestly implied; and they are accordingly urged as a decisive and absolute proof of the divinity of the doctrine and testimony of their performers, without ever taking into consideration the nature of the doctrine, or of the testimony to be confirmed. It is also shewn, that the scriptures have not recorded any instances of real miracles performed by the devil; in answer to the objections drawn from the case of the magicians in Egypt, from the appearance of Samuel, after his decease, to Saul, which was either the work of human imposture or a divine miracle, and from our Saviours's temptation in the wilderness, which the writer, to whom we now refer, considers as a divine vision. Miracles, considered as the peculiar works of God, afford a divine testimony to the person on whose account they are wrought, and to that doctrine or message, which he delivers in the name of God. And this proof from miracles of the divine commission, and doctrine of a prophet, is in itself decisive and absolute. It is also the most natural and agreeable to the common sense of mankind in all ages. It is the most easy and compendious proof of a new revelation. Miracles are farther a very powerful method of conviction, making a strong impression upon the heart, at the same time that they carry light to the understanding. Nor is the necessity of miracles less evident than their propriety and advantage, in attesting a divine commission and propagating a new revelation. They also serve to revive and confirm the principles of natural religion, and to recover men from those two opposite extremes of atheism and idolatry. Finally, the evidence of miracles, whether of power or knowledge, is the fittest to accompany a standing revelation; because it is not confined to one age or nation, but may be extended over the whole globe, and conveyed to the most distant generations. On the nature and design of miracles, already illustrated in this article, see Farmer's Dissertation on Miracles, &c. 8vo. 1771, passim.

On the other hand, Dr. Clarke, who allows that miracles may be wrought by other agents besides the Deity, observes that it cannot certainly be distinguished, by the miracle itself, whether any extraordinary interposition of some power superior to men be the immediate interposition of God himself, or of some good angel, or of some evil angel. The only possible ways, says this learned writer, by which a spectator may certainly and infallibly distinguish whether miracles be indeed the works either immediately of God himself, or of some good angel employed by him; and consequently the doctrine witnessed by the miracles be infallibly true and divinely attested: or whether, on the contrary, the miracles be the works of evil spirits, and consequently the doctrine a fraud and imposition upon men, are these: if the doctrine attested by miracles be in itself impious, or manifestly tending to promote vice; then, without all question, the miracles, how great soever they may appear to us, are neither wrought by God himself nor by his commission. If the doctrine, attested by miracles, be in itself indifferent, or such as cannot, by the light of nature and right reason alone, be certainly known whether it be true or false; and at the same time, in opposition to it, and in proof of the direct contrary doctrine, there be wrought other miracles, more and greater than the former, or at least attended with such circumstances as evidently shew the power, by which the latter are wrought, to be superior to the power that produced the former: then that doctrine, which is attested by the superior power, must necessarily be believed to be divine. This, he apprehends, was the case of Moses and the Egyptian magicians. (See MAGICIAN.) If, in the last place, the doctrine attested by miracles be such as, in its own nature and consequences, tends to promote the honour and glory of God, and the practice of universal righteousness among men; and yet nevertheless be not in itself demonstrable, nor could, without revelation, have been discovered to be actually true; and there is no pretence of more or greater miracles, on the opposite side, to contradict it: which is the case of the doctrine and miracles of Christ; then the miracles are unquestionably divine, and the doctrine must, without all controversy, be acknowledged as an immediate and infallible revelation from God. In order to obviate the objection, that we prove in a circle the doctrine by the miracles, and the miracles by the doctrine; he adds, that the miracles, in this way of reasoning, are not at all proved by the doctrine; but only the possibility and the good tendency, or at least the indifferency of the doctrine, are a necessary condition or circumstance, without which, the doctrine is not capable of being proved by any miracles. The doctrine must be in itself possible and capable of being proved, and then miracles will prove it to be actually and certainly true. Boyle's Lecture, Sermons, &c. p. 226, &c.

The sufficiency of the argument in attestation to the truth of Christianity, deduced from miracles, has been controverted by several sceptical writers; and particularly by Mr. Hume. It has been alleged, that experience is the ground of the credit we give to human testimony. Having found in past instances that men have informed us right, we are disposed to believe them in future instances; but this experience is by no means constant; for we often find that men prevaricate and deceive. On the other hand, what assures us of those laws of nature, in the violation of which the notion of a miracle consists, is, in like manner, experience. But this is an experience that has never been interrupted. A miracle, it has been said, is an event which, from

from its nature, is inconsistent with all the experience we ever had, and in the highest degree incredible and extraordinary. In the falshood of testimony, on the contrary, there is no such inconsistency, nor any such incredibility, scarcely any thing being more common. No regard, therefore, can be due to the latter, when it is applied as a proof of the former. According to this reasoning, applied to the case of miracles, we are to consider which is most likely, that such events should happen, or that men should either deceive or be deceived. And as there is nothing more unlikely than the former, or much more common than the latter, particularly where religion is concerned, it will be right to form a "general resolution, never to lend any attention to accounts of miracles, with whatever specious pretexts they may be covered." "It is," says Mr. Hume in his "Essay on Miracles," "a maxim worthy of our attention, that no testimony is sufficient to establish a miracle, unless the testimony be of such a kind, that its falshood would be more miraculous than the fact which it endeavours to establish. And even in that case, there is a marked distinction of arguments, and the superior only gives us an assurance suitable to that degree of force, which remains after deducting the inferior. When any one tells me that he saw a dead man restored to life, I immediately consider with myself, whether it be more probable that the person should either deceive or be deceived, or that the fact he relates should really have happened. I weigh the one miracle against the other, and according to the superiority which I discover, I pronounce my decision, and always reject the greater miracle. If the falshood of his testimony would be more miraculous than the event which he relates, then, and not till then, can he pretend to command my belief or opinion." For such reasons as these Mr. Hume asserts, "that the evidence of testimony, when applied to a miracle, carries falshood on the very face of it, and is more properly a subject of derision than of argument;" and that whoever believes the truth of the Christian religion "is conscious of a continued miracle in his own person, which subverts all the principles of his understanding, and gives him a determination to believe what is most contrary to custom and experience." The principles on which this objection is founded, says an excellent writer, Dr. Price, are chiefly, "that the credit we give to testimony is derived *solely* from experience:" "that a miracle is a fact *contrary* to experience:" "that the previous improbability of a fact is a proof against it, diminishing, in proportion to the degree of it, the proof from testimony for it;" and "that no testimony should ever gain credit to an event, unless it is more extraordinary that it should be false, than that the event should have happened." Our author, in his examination of these opinions, begins with considering the nature and foundation of that assurance which experience gives us of the laws of nature. After a variety of ingenious observations on the nature and degree of the assurance with regard to future events, which we derive from past experience of the course of nature, this writer states the result of the whole in the following manner. "Upon observing, that any natural event has happened often or invariably, we have only reason to expect that it will happen again, with an assurance proportioned to the frequency of our observations. But we have no *absolute proof* that it will happen again in any future trial; nor the least reason to believe that it will always happen. For aught we know, there may be occasions on which it will fail, and secret causes in the frame of things which *sometimes* may counteract those by which it is produced." In examining the ground of the regard we pay to human testimony, our author concludes, that it is not experience only, or that kind of experience to which we owe our expectation of natural events, the causes of which are unknown to us. We feel in ourselves, that a regard to truth is one principle in human nature; and we know, that there must be such a principle in every reasonable being; and to this chiefly is owing the credit we give to human testimony. It is plain and capable of the most satisfactory proof, that there is a great difference between the conviction produced by testimony, and the conviction produced by experience, and the one is capable of being carried much higher than the other. Besides, the greatest part of what is commonly called experience is merely the report of testimony. "Our own experience," says Dr. Adams, "reaches around, and goes back but a little way; but the experience of others, on which we chiefly depend, is derived to us wholly from testimony." In proportion, therefore, as we weaken the evidence of testimony, we weaken also that of experience; and in comparing them we ought in reason to oppose to the former, only what remains of the latter after that part of it which is derived from the former, that is, after much the greatest part of it, is deducted. From this reasoning it follows, that there is no absurdity in using *testimony* for proving a *miracle*. This is not using a *feebler* experience to overthrow another of the same kind, which is *stronger*; but using an argument to establish an event, which yields a direct and positive proof, and is capable of producing the strongest conviction, to overthrow another founded on different principles, and which, at best, can prove no more than that, previously to the event, there would have appeared to us a presumption against its happening.

Moreover, a miracle cannot, with propriety, be styled an event *contrary* to experience; as Mr. Hume asserts. A miracle, says our author, is more properly an event *different* from experience than *contrary* to it; nor can it be proper to assert, as Mr. Hume does, that in every case of a miracle supported by testimony, there is a contest of two opposite experiences, the strongest of which ought always to determine our judgments. In Mr. Hume's argument there is, as Dr. Price intimates, a fundamental error: it is where he declares, that, "if, previously to an event, there was a greater probability *against* its happening, than there is *for* the truth of the testimony endeavouring to establish it, the former destroys the latter, and renders the event unlikely to have happened in proportion to its superiority." This is evidently a fundamental point in Mr. Hume's objection; or, in other words, in the principle, that no testimony should engage our belief, except the improbability in the falshood of it is greater, than that in the event which it attests. In order to evince the erroneousness of this principle, what our author wishes to be considered is, the degree of improbability which lies against almost all the common facts, independently of the evidence of testimony for them. In many cases of particular histories, which are immediately believed on the slightest testimony, there would have appeared to us, previously to this testimony, an improbability of almost infinity to one against their reality, as any one must perceive, who will think how sure he is of the falshood of all facts, that have *no* evidence to support them, or which he has only *imagined* to himself. It is then very common for the slightest testimony to overcome an almost infinite improbability. That this is the case our author has rendered evident by a train of satisfactory reasoning, which we have not room to introduce. For further particulars we must refer to the author himself, *ubi infra*.

Archdeacon Paley has, with his usual perspicuity, examined the objection of Mr. Hume against the credibility of miracles,

miracles, which we have above ftated. Having premifed that there is no antecedent improbability of a revelation from God, but that the contrary is the cafe; and that there is no way in which fuch a revelation can be made but by miracle, it is not improbable that miracles fhould be wrought. The improbability which arifes from the miraculous nature of the things related is not greater than the original improbability that fuch a revelation fhould be imparted by God. Admitting then, that a revelation is not improbable, and that if there be a revelation, there muft be miracles, the objection that no human teftimony can render miracles credible muft appear to be unfounded. Mr. Hume's principle, concifely ftated, is this; that the truth of a miracle is contrary to experience, but it is not contrary to experience that teftimony fhould be falfe. Our author obferves that the term "experience," and the phrafes "contrary to experience," or "contradicting experience," are ambiguous, and require explanation. Strictly fpeaking, the narrative of a fact is *then* only contrary to experience, when the fact is related to have exifted at a time and place, at which time and place, we, being prefent, did not perceive it to exift. In this cafe the affertion is contrary to experience, properly fo called; nor is it of any confequence, whether the fact be of a miraculous nature or not. This is a contrariety which no evidence can furmount. But this is not the experience, nor contrariety, which Mr. Hume meant to exprefs in his objection; fhort of this, no intelligible fignification can be affixed to the term "contrary to experience," but one, *viz.* that of not having experienced any thing fimilar to the thing related, or fuch things not being generally experienced by others. Now the improbability which arifes from the want of experience, not contradiction to it, is only equal to the probability there is, that if the thing were true, we fhould experience things fimilar to it, or that fuch things would be generally experienced. Suppofing then that miracles were wrought upon the firft promulgation of Chriftianity, when nothing but miracles could decide its authority, is it certain that fuch miracles would be repeated fo often, and in fo many places, as to become objects of general experience? Is it a probability approaching to certainty? Is it a probability of any great ftrength or force? Is it fuch as no evidence can encounter? And yet this probability is the exact *converfe*, and therefore the exact meafure of the improbability which arifes from the want of experience, and which Mr. Hume reprefents as invincible by human teftimony. The force of experience, continues our author, is founded in the prefumption, either that the courfe of nature is invariable, or that, if it be ever varied, variations will be frequent and general. Has the neceffity of this alternative been demonftrated? Calling the courfe of nature the agency of an intelligent Being, is there any good reafon for judging this ftate of the cafe to be probable? Ought we not rather to expect, that fuch a Being, upon occafions of peculiar importance, may interrupt the order which he had appointed, yet that fuch occafions fhould return feldom; that thefe interruptions confequently fhould be confined to the experience of a few; that the want of it, therefore, in many, fhould be matter neither of furprife nor objection? But it is faid, that in our account of miracles, we affign effects without caufes, or we attribute effects to caufes inadequate to the purpofe, or to caufes of the operation of which we have no experience. Of what caufes, we may afk, and of what effects, does the objection fpeak? If it be anfwered that, when we afcribe the cure of the palfy to a touch, of blindnefs to the anointing of the eyes with clay, or the raifing of the dead to a word, we lay ourfelves open to this imputation; we reply, that we afcribe no fuch effects to fuch caufes. We perceive no virtue or energy in thefe things more than in other things of the fame kind. They are merely figns to connect the miracle with its end. The effect we afcribe fimply to the volition of the Deity; of whofe exiftence and power, not to fay of whofe prefence and agency, we have previous and independent proof. We have therefore all we feek for in the works of rational agents, a fufficient power and an adequate motive. In a word, once believe that there is a God, and miracles are not incredible. Mr. Hume, as our author proceeds, ftates the cafe of miracles to be a conteft of oppofite improbabilities, that is to fay, a queftion whether it be more improbable that the miracle fhould be true, or the teftimony falfe. In this ftatement, however, there is a want of argumentative juftice; becaufe, in defcribing the improbability of miracles, he fuppreffes all thofe circumftances of extenuation, which refult from our knowledge of the exiftence, power, and difpofition of the Deity, his concern in the creation, the end anfwered by the miracle, the importance of that end, and its fubferviency to the plan purfued in the works of nature. As Mr. Hume has reprefented the queftion, miracles are alike incredible to him who is previoufly affured of the conftant agency of a divine Being, and to him who believes that no fuch being exifts in the univerfe. They are equally incredible, whether related to have been wrought upon occafions the moft deferving, and for purpofes the moft beneficial, or for no affignable end whatever, or for an end confeffedly trifling or pernicious. This furely cannot be a correct ftatement. In adjufting alfo the other fide of the balance, the ftrength and weight of teftimony, the author has provided an anfwer to every poffible accumulation of hiftorical proof, by telling us, that we are not obliged to explain how the ftory or the evidence arofe. The archdeacon thinks that we are obliged to do this. The exiftence of the teftimony is a phenomenon: the truth of the fact folves the phenomenon. If we reject this folution, we ought to be able to recur to fome other; and none even by our adverfaries can be admitted, which is not confiftent with the principles that regulate human affairs and human conduct at prefent, or which makes men *then* to have been a different kind of beings from what they are now. Our author adds; the fhort confideration, which, independently of every other, convinces me, that there is no folid foundation in Mr. Hume's conclufion, is the following: when a theorem is propofed to a mathematician, the firft thing he does with it is to try it upon a fimple cafe; and if it produce a falfe refult, he is fure that there muft be fome miftake in the demonftration. Let us proceed in this way with what may be called Mr. Hume's theorem. "If 12 men, whofe probity and good fenfe I had long known, fhould ferioufly and circumftantially relate to me an account of a miracle wrought before their eyes, and in which it was impoffible that they fhould be deceived; if the governor of the country, hearing a rumour of this account, fhould call thefe men into his prefence, and offer them a fhort propofal, either to confefs the impofture, or fubmit to be tied up to a gibbet; if they fhould refufe with one voice to acknowledge that there exifted any falfhood or impofture in the cafe; if this threat were communicated to them feparately, yet with no different effect; if it was at laft executed; if I myfelf faw them, one after another, confenting to be racked, burnt, or ftrangled, rather than give up the truth of this account; ftill, if Mr. Hume's rule be my guide, I am not to believe them. Now I undertake to fay, that there exifts not a fceptic in the world who would not believe them; or who would defend fuch incredulity."

Having explained the nature and evinced the credibility of miracles in general, we might take occafion to illuftrate the evidence which the miracles, that are recorded by the founders and advocates of Chriftianity, afford in atteftation of its truth and

and divine origin. Admitting the credibility of miracles in general, and of the Christian miracles in particular, we might allege many direct, collateral, and presumptive arguments in proof of their reality. The miracles which the New Testament records, are in their own nature and design worthy of the wisdom, power, and benevolence to which they are ascribed. If we consider these miracles in themselves, in their number and variety as well as their nature, in the state and circumstances of those who were the objects of them, in the unostentatious and yet public manner of their being wrought, in the multitude and also the disposition and character of those who witnessed them, in the extent and permanence of their effects, and in their connection with the reception and prevalence of the religion which they were intended to introduce and establish, we cannot question their reality: we cannot discover any traces of collusion and deceit: we cannot hesitate in allowing them to be such as the evangelical historians have described and recorded. As for the historians themselves, their character and conduct, their labours and sufferings undergone and endured in attestation to the truth of the facts which they relate, and the death which they preferred to the infamy of renouncing their belief of them, evince, in the most satisfactory manner, their integrity, and preclude every suspicion of fraud and imposture. This testimony, transmitted to us with every attendant circumstance of credibility, claims our confidence, and whilst we believe the reality of the miracles which they record, we cannot demur in tracing the religion which, by their writings and teaching, they have communicated to the world, to a divine origin. But we must desist from enlarging, and refer our readers to Price's Four Dissertations, Diss. 4. Paley's View of the Evidences of Christianity, vol. i. Adams's Ess. on Miracles. Bishop Douglas's Criterion. Campbell's Dissertation on Miracles. See CHRISTIAN *Religion*, REVELATION, *New* TESTAMENT, and other similar articles in the Cyclopædia.

The Romans attribute miracles to their emperors Adrian and Vespasian. The church of Rome abounds in miracles: if we believe their writers, some of their monks have wrought more miracles than all the apostles; and this without any visible necessity for them.

Mr. Hume has confronted the miracle of Vespasian related by Tacitus, that performed in a Spanish church, and related by cardinal de Retz, and the cures said to be performed at the tomb of the abbé Paris, in the early part of the last century, with those of the New Testament. With respect to the latter miracles, we observe, that the patients who frequented the abbé's tomb were so affected with their devotion, their expectation of relief, the place, the solemnity, and above all, by the sympathy of the surrounding multitude, that many of them were thrown into violent convulsions, which convulsions, in certain instances, produced a removal of disorders, depending upon obstruction. The above account may now be admitted with less difficulty, because the same or similar effects have been experienced in the operations of *animal magnetism*. See on the subject of these miracles, Douglas's Criterion.

As full as the Romish church has pretended to be of saints, it has been a rule with them, that none should be ever canonized till there be a good proof of their having wrought miracles. So that were all those allowed to be good miracles, and to have happened out of the common order of nature, they are so numerous, that one would be tempted to think there was no order or law of nature at all.

Some Protestant writers have maintained, that the power of working miracles was exercised in the Christian church during the three or four first centuries; in proof of which they allege that of the thundering legion, &c. But Dr. Middleton, in his Free Inquiry into the miraculous Powers, which are said to have subsisted in the Christian church, &c. has maintained a very different opinion. And it must be acknowledged, that the evidence of the facts is, to say the least of it, very doubtful.

The many and stupendous miracles which are said to have been wrought by the Christian missionaries, who were sent to convert the barbarous nations, in the eighth century, have lost, in our times, the credit they obtained in former ages.

St. Augustine is a strong advocate for miracles. He mentions several, of which he was an eye-witness; and others, of which he was informed by those that were. In the single city of Hippo, he tells us there were seventy miracles wrought in the space of two years, on the building of a chapel in honour of St. Stephen. There are those, however, who set aside the authority of all miracles; thinking it unbecoming the wisdom of God to establish such laws, as that he should find it frequently necessary to supersede. And as the former, from the avowed authority of some miracles, fetch an argument for the truth of all, pleading those which are allowed as well as those which are questioned; so these allege the false ones very unfairly, as conclusions against all.

MIRADOUX, in *Geography*, a town of France, in the department of the Gers, and chief place of a canton, in the district of Lectoure; 7 miles N.E. of Lectoure. The place contains 1655, and the canton 6343 inhabitants, on a territory of $157\frac{1}{2}$ kiliometres, in 12 communes. N. lat. 44°. E. long. 0° 50'.

MIRAFLORES, a town of South America, in the province of Tucuman, on the Salado; 80 miles N.N.E. of St. Miguel de Tucuman.—Also, a town of Peru, in the audience of Lima; 8 miles S. of Lima.

MIRAGE, the name given by the French sailors to an optical phenomenon, on which M. Monge read a memoir to the institute at Cairo, during the French invasion of Egypt. It often happens at sea, that a ship seen at a distance appears as if painted in the sky, and not to be supported by the water. A similar effect was observed by the French in the course of their march through the desert: the villages seen at a distance seemed to be built on an island in the middle of a lake. In proportion as they approached, the apparent surface of the water became narrower; when they were only at a small distance, it disappeared, and the same illusion began, in regard to the next village. M. Monge ascribes this effect to a diminution of the density of the lower stratum of the atmosphere. This diminution in the desert is produced by the increase of heat, arising from that communicated by the rays of the sun to the sand, with which this stratum is in immediate contact. At sea it takes place when, by particular circumstances, such as the action of the wind, the lower stratum of the atmosphere holds in solution a greater quantity of water than the other strata. In this state of things the rays of light, which come from the lower parts of the heavens, having arrived at the surface that separates the less dense stratum from those above it, do not pass through that stratum, but are reflected, and paint in the eye of the observer an image of the heavens, which appearing to him to be below the horizon, he takes it for water, when the phenomenon occurs at land. If he is at sea, he thinks he sees in the heavens all the objects which float on that part of the surface occupied by the image of the heavens. This phenomenon has been considered and explained by several English philosophers. See *Horizontal* REFRACTION.

MIRAGOANE, in *Geography*, a town on the north side of the south peninsula of the island of St. Domingo, and south side of the bight of Leogane, at the head of a bay of its name; 15 miles W. of Petit Goave.

MIRALETUS, in *Ichthyology*, a name given to the species of ray, commonly called by others *raja oculata*. See Raja *Miraletus*.—Also, a name given by Bellonius and others to the Raja *Oxyrinchus*; which see.

MIRAMACHI, or Mirachi, in *Geography*, a port, bay, and river, on the north coast of New Brunswick. The port is at the entrance of the bay. In the river there is a salmon fishery.

MIRAMBEAU, a town of France, in the department of the Lower Charente, and chief place of the district of Jonsac; 12 miles S. of Pons. The place contains 2170, and the canton 15,117 inhabitants, on a territory of 242½ kiliometres, in 19 communes.

MIRANA, a small island in the North Pacific ocean. N. lat. 62° 35′. E. long. 190° 34′.

MIRANDA, a town of Spain, in Navarre; 13 miles S.E. of Estalla.—Also, a town of Naples, in the country of Molise; 11 miles W. of Molise.

Miranda *de Corvo*, a town of Portugal, in the province of Beira, containining about 2700 inhabitants; 15 miles S.E. of Coimbra.

Miranda *de Duero*, a town of Portugal, in the province of Tras-los-Montes, situated in a barren mountainous country on the Duero, on the frontiers of Spain; the see of a bishop. It is but a poor mean town; 28 miles S.E. of Braganza. N. lat. 41° 24′. W. long. 5° 56′.

Miranda *d'Ebro*, a small town of Spain, in Old Castile, beautifully situated on the Ebro, over which is a noble bridge of eight arches. It contains a large square, embellished with fountains. It is environed by mountaine, on whose brow are the remains of a castle, and the ruins of several towers, which formerly guarded access to it. A copious stream flows from the mountain, which serves to work several mills in its vicinity. The town was erected into an earldom, in the 14th century, by Henry IV., in favour of Don Diego de Zuniga, and is now governed by its alcade; 32 miles N.E. of Burgos.

MIRANDE, a town of France, and principal place of a district, in the department of the Gers. The place contains 1558, and the canton 10,316 inhabitants, on a territory of 292½ kiliometres, in 49 communes. N. lat. 43° 31′. E. long. 0° 28′.

MIRANDELA, a town of Portugal, in the province of Tras-los-Montes; 30 miles S.W. of Braganza. N. lat. 41° 25′. W. long. 6° 58′.

MIRANDOLA, *Duchy of*, a small principality of Italy, almost surrounded by the duchy of Mantua. This principality shared the fate of Modena, and became a part of the Cisalpine republic, now the kingdom of Italy.—Also, a city of Italy, in the department of Panaro; lately capital of a duchy united with Modena, strong, and defended by a citadel; the see of a bishop. It contains, besides the cathedral, 15 churches; 14 miles N.N.E. of Modena. N. lat. 44° 50′. E. long. 11° 5′.

MIRANO, a town of Italy, in the Paduan, on the river Musan, containing about 3120 inhabitants; 12 miles N.E. of Padua.

MIRAPORVOS, a rocky islet among the Bahamas, near the south-west coast of Crooked island. N. lat. 21° 55′. W. long. 74° 46′.

MIRAPOUR, a town of Bengal; 30 miles E. of Burdwan.—Also, a town of Hindoostan, in the circar of Schaurunpour; 15 miles N. of Merat.

MIRASOLE, a town of Italy, in the department of the Mincio; 9 miles S.S.E. of Mantua.

MIRAVALLES, a town of Spain, in the province of Biscay; 9 miles S. of Bilboa.

MIRAVEL, a town of Spain, in New Castile, on the side of a hill, defended by a strongly fortified castle; 12 miles S.S.W. of Placencia.

MIRAW, or Merow, a town of Moravia, in the circle of Olmutz; 22 miles N.W. of Olmutz.

MIRAY Bay, a bay on the coast of the island of Cape Breton. Large vessels may go up six leagues, have good anchorage, and lie secure from all winds. N. lat. 46° 5′. W. long. 59° 49′.

MIRBELIA, in *Botany*, named by the writer of this article, in honour of Mons. Mirbel, Superintendant of the botanic garden at Malmaison, member of various learned academies, and author of several excellent works on the anatomy and physiology of vegetables. His elucidations of their reticulated structure having excited much attention, the present plant, remarkable for the reticulated aspect of its leaves, was judged more particularly suited to perpetuate his name. Smith in Sims and Konig's Annals of Botany, v. 1. 511. Brown in Ait. Hort. Kew. ed. 2. v. 3. 21.—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, sect. 4. Juss.

Gen. Ch. *Cal.* Perianth inferior, bell-shaped, two-lipped, without appendages; somewhat angular at the base: upper lip of two abrupt, oblique, parallel segments; lower of three lanceolate, acute, equal ones, dilated at the base, rather shorter than the upper: permanent. *Cor.* papilionaceous, of five petals, about twice the length of the calyx; standard inversely heart-shaped, recurved, with a short, broad, linear claw; wings lanceolate-oblong, rather shorter than the standard, with a tooth at the upper edge; keel shorter than the wings, of two cohering, half-ovate petals, with linear claws. *Stam.* Filaments ten, awl-shaped, equal, contained within the keel, inserted into the receptacle; anthers roundish, incumbent. *Pist.* Germen superior, ovate-oblong; style thick and short, bent upwards; stigma capitate. *Peric.* Legume heart-shaped, pointed, tumid, with a groove at each side, of two cells, at length separating from each other; the partition double, from both the inflexed margins of each valve. *Seeds* solitary, attached to the lower edge of each valve, oval, compressed, with a circular bordered scar.

Eff. Ch. Calyx five-cleft, two-lipped. Corolla papilionaceous. Style reflexed. Stigma capitate. Legume of two cells, tumid, with two seeds; the partition double.

1. M. *reticulata*. Reticulated Mirbelia. Sm. as above. Tr. of Linn. Soc. v. 9. 265. Venten. Malmais. t. 119. (Pultenæa rubiæfolia; Andr. Repos. t. 351.)—Leaves linear-lanceolate, veiny.—Native of the neighbourhood of Port Jackson, New South Wales. *Dr. White*. It was very early raised from seeds in this country, and is kept in the green-house, in light sandy peat earth, with little water in winter, but as much air as possible; flowering from May to August, the second year after being sown. The *stem* is shrubby, much branched, and very bushy, smoothish, leafy, angular; the branches mostly ternate, straight, and spreading. *Leaves* almost always three in a whorl, rarely opposite only, on very short broad footstalks, spreading, an inch long, linear-lanceolate, sometimes elliptical and shortened, smooth, revolute, slightly crenate or wavy, tipped with a spine, furnished with one rib and many transverse veins; paler and most opaque beneath. *Flowers* in little axillary and terminal tufts, on short *stalks*; with a pair of linear *bracteas* in the middle of each stalk. *Corolla* light purple, with a radiating reddish stain at the base of the standard. *Legume* a quarter of an inch long, grey, smooth, transversely veined. It is curious that this shrub should ever have been mistaken

mistaken for a *Rubia*, which was actually the case before it flowered.

2. M. *dilatata*. Lobed-leaved Mirbelia. Brown in Ait. Hort. Kew. n. 2.—Leaves wedge-shaped, dilated and three-cleft at the extremity.—Found by Mr. Brown on the south-west coast of New Holland. This species was sent to Kew, in 1803, by Mr. Peter Good, and flowers in the green-house in May and June. The *stem* is shrubby. We have seen no specimen, nor is any account given of the colour of the *flowers*.

MIRCHOUR, in *Geography*, a town of Hindoostan, in Golconda; 20 miles S.S.E. of Canoul.

MIREBALAIS, an interior town in the French part of the island of St. Domingo; 30 miles N. of Port au Prince.

MIREBEAU, a town of France, in the department of the Coté d'Or, and chief place of a canton, in the district of Dijon; 13 miles N.E. of Dijon. The place contains 1100, and the canton 8578 inhabitants, on a territory of 257½ kiliometres, in 22 communes.—Also, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Poitiers; 12 miles N.N.E. of Poitiers. The place contains 2021, and the canton 7096 inhabitants, on a territory of 192½ kiliometres, in 14 communes. N. lat. 46° 47'. E. long. 0° 16'.

MIRECOURT, a town of France, and principal place of a district, in the department of the Vosges; 13 miles N.W. of Epinal. The place contains 5084, and the canton 11,757 inhabitants, on a territory of 175 kiliometres, in 28 communes. N. lat. 43° 18'. E. long. 6° 13'.

MIREMONT, a town of France, in the department of the Dordogne; 10 miles S.W. of Montignac.—Also, a town of France, in the department of the Upper Garonne; 7 miles S.E. of Muret.

MIRENI, a town of Walachia, on the Ardgis, near its confluence with the Danube; 30 miles S. of Bucharest.

MIREPOIX, a town of France, and principal place of a district, in the department of the Arriege; 18 miles N.E. of Tarascon. The place contains 2819, and the canton 13,589 inhabitants, on a territory of 335 kiliometres, in 37 communes. N. lat. 43° 5'. E. long. 1° 56'.

MIREVELT, Michael Janson, in *Biography*, a portrait painter, born at Delft in 1568. The extreme resemblance of his pictures, the freshness of their colour, and the neatness of their execution, procured Mirevelt a most extraordinary influx of professional occupation; so much, that he is reported by Houbraken to have painted 5000 portraits: for the smallest of which, merely a head, he was paid about 15*l.* sterling; and those of larger sizes in proportion.

He certainly was a very ingenious artist, and, where the talents of Rubens were unknown, must have appeared a luminary of his day; but the superior taste and freedom exhibited in the works of the latter, and afterwards in those of his extraordinary pupil Vandyke, render the works of Mirevelt tame and insipid. He died in 1641.

Mirevelt, Peter, son of the former, and a painter of the same taste, style, and study. By many he is thought fully equal to his father.

MIRGONDA, in *Geography*, a town of Hindoostan, in Dowlatabad; 25 miles S.W. of Beder.

MIRGOROD, a town of Russia, in the government of Kiev; 100 miles E.S.E. of Kiev. N. lat. 50°. E. long. 32° 54'.

MIRIAM, in *Sacred History*, the sister of Aaron, and a prophetess. When Moses had finished his pious effusions in the first hymn on record, after the safe passage of the Red sea, at the head of the whole people of Israel, just escaped from bondage, he was seconded on this occasion by Miriam, "who took a timbrel in her hand, and all the women went out after her with timbrels and with dances, and Miriam answered them, Sing ye to the Lord," &c.

Here is an early instance of women being permitted to bear a part in the performance of religious rites, as well as of vocal music being accompanied by instrumental, and by what was called *dancing*, which was probably nothing more than moving or marching in regulated steps and gesture.

MIRJANAGORE, in *Geography*, a town of Bengal; 15 miles S. of Moorley.

MIRICK, Cape, a cape on the west coast of Africa. N. lat. 19°. W. long. 6° 5'.

MIRIOSITO, a town of European Turkey, in Romania; 24 miles N.E. of Gallipoli.

MIROBRIGA, in *Ancient Geography*, a town of Spain, the scite of which is now occupied by Cividad *Rodrigo*; which see. This town of Leon was built in the reign of Ferdinand II, about the 13th century, and was made a rampart against Portugal. It is situated in a flat and tolerably beautiful country, producing abundance of the necessaries of subsistence. Its plains extend five leagues to the north, and are terminated by a chain of mountains, which are branches of those of Bejar, Pena de Francia, and Geta. The town is fortified, and is the see of a bishop. It has seven gates, and its streets are tolerably regular. Its population amounts to about 10,000 inhabitants. It has a cathedral, a collegiate church, six parish churches, five convents of monks, four of nuns, one seminary, and two hospitals. The river Ague passes close to the town. The ancient Roman aqueduct is destroyed; but the inhabitants have constructed another, which conveys the water requisite for the town and watering of the trees, through the space of three leagues. There are also some fountains out of the walls; and in the extent of the diocese are some medicinal waters, copper, lead, iron, and even gold mines.

MIROPEL, in *Geography*, a town of the duchy of Warsaw; 40 miles W.N.W. of Berdiczow.

MIROPOLBE, a town of Russia, in the government of Cherkov; 88 miles N.N.W. of Charkov. N. lat. 51° 22'. E. long. 34° 34'.

MIROUETTE, in the *Manege*, is used for a dapple-bay.

MIROW, in *Geography*, a town of the duchy of Mecklenburg; 44 miles N. of Spandau.

MIROWITZ, a town of Bohemia, in the circle of Prachatitz; 18 miles N.N.E. of Strakonitz.

MIRROR, a *speculum*, or body, which exhibits the images of objects presented to it by reflection.

The use of mirrors is very ancient. Mention is made of brazen mirrors, or looking-glasses, in Exodus, xxxviii. 8. where Moses is said to have made a "brazen laver, or *bason*, of the looking-glasses of the women continually assembled at the door of the tabernacle." It is true some modern commentators will not allow the mirrors themselves to have been brass; but of glass, only set or framed in brass. But the most learned among the rabbins do all allow, that in those times the mirrors made use of by the Hebrew women in dressing their heads were of metal; and that the devout women, mentioned in this passage, made presents to Moses of all their mirrors, to make the brazen laver. See the Jesuit Bonfrerius's comment on this text. See Glass.

It might likewise be proved, that the ancient Greeks made use of brazen mirrors, from divers passages among the ancient poets.

Mirror, in the more confined sense of the word, is peculiarly used to signify a smooth surface of glass, tinned and quick-

quickfilvered on the back-fide; which exhibits the images of objects oppofed to it. See LOOKING-GLASS.

MIRROR, in *Catoptrics*, denotes any polifhed body impervious to the rays of light, and which of confequence reflects them equally.

Thus water in a deep well or river, and fmooth polifhed metals, are ranked among the number of mirrors.

In this fenfe, the doctrine of mirrors makes the fubject of catoptrics.

Mirrors are made either of glafs, coated with an amalgam of mercury and tin, or of metal, as of platina, of filver, or of an alloy of copper and tin, to which a little arfenic and filver are fometimes added. Mirrors of metal are more perfect than thofe of glafs, becaufe they are free from the inconvenience of a double reflection; but they are more expenfive, and are liable to tarnifh. Where a large mirror is required, with only a weak reflection, we may employ a fingle furface of glafs, the back of the piece being covered with a black coating of fome fubftance differing little from glafs in its refractive denfity, by means of which the fecond reflection is avoided. See SPECULUM.

The doctrine of mirrors is founded on the following general principles.—1. Light reflected from any mirror, or fpeculum, makes the angle of incidence equal to that of reflection; which fee demonftrated under the word REFLECTION.

Hence, a ray of light, as H B, (*Plate* XIII., *Optics*, *fig.* 1.) falling perpendicularly on the furface of a fpeculum D E, will be reflected back upon itfelf: as we find by experience it actually is.

From the fame point of a mirror, therefore, B, there cannot be feveral rays reflected on the fame point; fince, in that cafe, all the angles of incidence muft be equal to the fame angle of reflection C B G, and therefore to each other; which is abfurd. Nor can the ray A B be reflected to two or more points; fince, in that cafe, all the angles of reflection would be equal to the fame angle of incidence A B F; which is likewife abfurd.

2. From every point of a mirror, are reflected rays thrown on it from every point of a radiant object. Since then rays coming from different parts of the fame object, and ftriking on the fame point of the mirror, cannot be reflected back to the fame point; the rays which flow from different points of the fame radiating object are again feparated after reflection: fo that each point fhews whence it came.

Hence it is, that the rays reflected from mirrors exhibit the objects to view. Hence alfo, it appears, that rough uneven bodies muft reflect the light in fuch a manner as that rays coming from different points will be blended or thrown confufedly together.

Mirrors may be divided into *plane*, *concave*, *convex*, *cylindrical*, *conical*, *parabolical*, and *elliptical*.

MIRRORS, *Plane*, are thofe which have a plane or flat furface.

Thefe, by a popular name, we call *looking-glaffes*.

For the manner of making plane mirrors, or fpecula, fee LOOKING-GLASS.

MIRRORS, *Laws and Phenomena of Plane*. 1. In a plane mirror, every point of an object, as A, (*Plate* XIII. *Optics*, *fig.* 2.) is feen in the interfection B, of the cathetus of incidence A B, with the reflected ray C B.

Let C D and F E be two reflected rays, correfponding to the incident rays A D, A E: then, fince the vertical angle C D G = E D B; and the angle of reflection C D H = A D G the angle of incidence, A D H will be = C D G = E D B. And H E F = D E B, and H E F = A E G, therefore D E B = A E G. But A E G + A D E, as well as B E D + B D E, are lefs than two right angles; confequently the reflected rays F E and C D meet in B, and in the equiangular triangles A D E and D E B, having D E common, D B = D A. Wherefore, fince the angle B D G = C D H = A D G, the angles at G will be equal, and confequently A B perpendicular to H G: *i. e.* A B is the cathetus of incidence: and, therefore, the reflected rays F E and C D meet with the cathetus of incidence A B in the fame point B: and the radiant point A is feen in B.

Hence, 1. As all the reflected rays meet with the cathetus of incidence in B; by whatever reflected ray the radiant point A be feen, it will ftill appear in the fame place. Confequently, any number of perfons, viewing the fame object in the fame mirror, will all fee it in the fame place behind the mirror. And hence it is, that the fame object has only one image, and that we do not fee it double with both eyes.

Hence, alfo, the diftance of the image B, from the eye C, is compounded of the ray of incidence A D, and the reflected ray C D: and the object A radiates reflectedly in the fame manner as it would do directly, were it removed into the place of the image.

2. The image of a radiant point, B, appears juft fo far behind a plane mirror, as the radiant point is before it: becaufe A G = B G.

Hence, if the mirror H G be placed horizontally, the point A will feem fo much below the horizon, as it is really elevated above it; confequently, erect objects will appear as if inverted; and therefore men ftanding on their feet, as if on their heads. Or, if the mirror be faftened to the ceiling of a room, parallel to the horizon, objects on the floor will appear above the ceiling as much as they really are below it; and inverted.

3. In a plane mirror the images are perfectly fimilar, and equal to the objects; for every point of the object is feen in the cathetus of incidence, and the mirror bifects that part of it which is intercepted between the radiant point and its image. And hence the ufe of mirrors as looking-glaffes.

4. In a plane mirror, things on the right hand appear as on the left; and *vice verfâ*.

Hence, alfo, we have a method of meafuring any inacceffible altitude, by means of a plane mirror. Thus, the mirror being placed horizontally in C (*fig.* 3.), retire from it till fuch time as the top of the tree be feen in it. Meafure the height of the eye D E, the diftance of the ftation from the point of reflection E C, and the diftance of the foot of the tree from the fame: then to E C, C B, and E D, find a fourth proportional A B. This is the altitude fought.

5. If a plane mirror A E (*fig.* 4.) be inclined to the horizon E H, in an angle of 45 degrees, an object C B perpendicular to it will appear parallel, I K, and the horizontal object L B perpendicular in M K.

For produce B C till it meets the mirror in A; then as H is a right angle, and E = 45°, A will be = 45°: therefore, if from B be drawn B G perpendicular to the mirror A E, A B G will be = 45°; and A G = G B. Let G K be = G B, and the image of B will be in K; draw K A, and becaufe K G = G A and G a right angle, K will be = 45°, and therefore K A parallel to E H. In the fame manner it may be fhewn, that the point C would appear in I, and confequently the image I K will be parallel to the horizon E H; and *vice verfâ*. Hence, the eye being placed beneath the mirror, the earth will appear perpendicularly over it: or if placed over the earth will appear

appear perpendicularly under it. Hence, alſo, a globe deſcending down a plane a little inclined, may, by means of a mirror, be exhibited as mounting up a vertical plane, to the great ſurprize of ſuch as are unacquainted with catoptrics. And hence we have a method of repreſenting ourſelves as if flying: for a mirror inclined to the horizon under an angle of 45°, we have obſerved, will repreſent vertical objects as if horizontal; conſequently, a large mirror being ſo diſpoſed, as you advance towards it, you will ſeem to move horizontally; and nothing will be wanting to the appearance of flying, but to ſtrike out the arms and legs. It muſt be added, however, that as the floor is elevated along with you, your feet will ſtill be ſeen to walk as along a vertical plane. To deceive the eye entirely, therefore, it muſt be kept from the feet.

6. If the object A B (*fig.* 5.) be parallel to the ſpeculum C D, and equally diſtant from it, with the eye; the reflecting line C D will be half the length of the object A B.

Let the eye O be in the object A B, or let the ſpectator view himſelf in a glaſs. Since A B is parallel to C D, the image G H will be parallel to it likewiſe. From O let fall O L perpendicular to C D, which, continued to I, will be alſo perpendicular to G H; therefore, O L and O I will be the reſpective altitudes of the triangles O C D and O G H, which triangles, having the angles $x = o$ and $u = y$, are ſimilar: conſequently C D : G H :: O L : O I; and as O L $= \frac{1}{2}$ O I, by art. 2. above, C D will be $= \frac{1}{2}$ G H $= \frac{1}{2}$ A B.

And hence, to be able to ſee the whole body in a plane mirror, its height and breadth muſt be half your height and breadth. Conſequently the height and breadth of any object to be ſeen in a mirror being given, we have alſo the height and breadth of the mirror in which the whole object will appear, at the ſame diſtance with the eye.

Hence, alſo, as the length and breadth of the reflecting part of the ſpeculum are ſubduple of thoſe of the object to be reflected; the reflecting part of the mirror is to the ſurface reflected in a ſubquadruple ratio. Conſequently, the reflecting portion being a conſtant quantity, if in any place you ſee the whole body in a mirror, you will ſee it in every other place, whether you approach nearer or recede farther from it.

7. If an object A B (*fig.* 6.) be parallel to the mirror I F; the length of the reflected line A B is to the reflecting part of the ſpeculum C D as the ſum of the incident and reflected rays B D + D O to the reflected ray O D; or as the ſum of the diſtances of the eye and of the object from the ſpeculum, *viz.* O I + B F to the diſtance of the eye O I. For G E : C D :: O E : O D; *i. e.* becauſe G E = A B, and D E = D B, A B : C D :: O D + D B : O D. Moreover, O E : O D :: O K : O I, therefore G E : C D :: O K : O I; conſequently, ſince I K = F E = B F, and G E = A B, we ſhall have A B : C D :: O I + B F : O I.

8. A ſpectator will ſee his own image as far beyond the ſpeculum as he is before it; and as he moves to or from the ſpeculum, his image will, at the ſame time, move towards or from him on the other ſide, but apparently with a double velocity, becauſe the two motions are equal and contrary. In like manner, if while the ſpectator is at reſt, an object be in motion, its image behind the ſpeculum will be ſeen to move at the ſame rate. And if the ſpectator moves, the images of objects that are at reſt will appear to approach or recede from him, after the ſame manner as when he moves towards real objects.

9. If ſeveral mirrors, or ſeveral fragments or pieces of a mirror, be all diſpoſed in the ſame place, they will only exhibit an object once.

10. If two plane mirrors, or ſpecula, meet in any angle, the eye, placed within that angle, will ſee the image of an object placed within the ſame, as often repeated as there may be catheti drawn determining the places of the images, and terminated without the angle.

Hence, as the more catheti, terminated without the angle, may be drawn as the angle is more acute; the acuter the angle, the more numerous the images. Thus Z. Traber found, at an angle of one-third of a circle, the image was repreſented twice, at $\frac{1}{4}$ thrice, at $\frac{1}{6}$ five times, and at $\frac{1}{12}$ eleven times.

Farther, if the mirrors be placed upright, and ſo contracted; or if you retire from them, or approach to them, till the images reflected by them coaleſce, or run into one, they will appear monſtrouſly diſtorted: thus, if they be at an angle ſomewhat greater than a right one, the image of your face will appear with only one eye; if the angle be leſs than a right one, you will ſee three eyes, two noſes, two mouths, &c. At an angle ſtill leſs, the body will have two heads. At an angle ſomewhat greater than a right one, at the diſtance of four feet, the body will be headleſs, &c. Again, if the mirrors be placed, the one parallel to the horizon, the other inclined to it, or declined from it, it is eaſy to perceive that the images will be ſtill more romantic. Thus, one being declined from the horizon to an angle of 144 degrees, and the other inclined to it, a man ſees himſelf ſtanding with his head to another's feet.

Hence it appears, how mirrors may be managed in gardens, &c. ſo as to convert the images of thoſe near them into monſters of various kinds; and ſince glaſs mirrors will reflect the image of a lucid object twice or thrice, if a candle, &c. be placed in the angle between two mirrors, it will be multiplied an infinite number of times. On theſe principles are founded various catoptric machines, ſome of which repreſent objects infinitely multiplied and diſtorted; others infinitely magnified, and ſet at vaſt diſtances.

MIRRORS, *Burning*. See BURNING-*Glaſs*.

MIRRORS, *Convex*, are thoſe whoſe ſurface is convex.

Note, by *convex* ſurfaces, authors generally mean ſuch as are *ſpherically convex*.

Manner of preparing or making convex Specula, or *Mirrors.* —There are various methods uſed by divers artiſts; particularly as to the matter or compoſition for the ſilvering. One of the beſt that is known is given us by Wolfius, thus:

Melt one part of tin, another of biſmuth, together; and to the melted maſs add two parts of mercury: as ſoon as the mercury begins to evaporate into ſmoke (which it preſently does), the whole compoſt is to be thrown into cold water, and when well cooled the water decanted off. The mixture is then to be ſtrained through a linen cloth two or threefold; and what is thus ſeparated, poured into the cavity of a glaſs ſphere: this ſphere is to be turned gently round its axis till the whole ſurface is covered, the reſt being reſerved for future uſe.

If the ſphere were of coloured glaſs, the mirror will be ſo too. And in the ſame manner may conic, elliptic, cylindric, and other mirrors, be made.

How they may he made of metal, ſee under *Concave* MIRROR. See alſo SPECULUM.

MIRRORS, *Laws or Phenomena of Convex.* 1. In a ſpherical convex mirror H C I (*fig.* 7.), the reflected ray E M concurs

concurs with the cathetus of incidence D L, and the incident ray D N with the cathetus of reflection E L, between the tangent A B, and the centre L. For the perpendiculars, or catheti of incidence, obliquation, and reflection, are in the plane of reflection, and, therefore, in the plane which touches the speculum in the point of incidence C; the tangent A C makes a right angle with the cathetus of obliquation F C; but the reflected ray E C, or C M, makes with it an acute angle *u*, and, therefore, falls between the tangent A C, and the cathetus of obliquation C L. Wherefore, since C L and D L meet in the centre L, the reflected ray E M ought to intersect the cathetus of incidence D L between the tangent and the centre. In the same manner it is shewn, that the incident ray D N ought to meet with the cathetus of reflection between the tangent and the centre. Hence, the image of a radiant point appears between the centre and the tangent, because it appears in the concourse of the reflected ray and cathetus of incidence.

2. In a spherical convex mirror, the cathetus of incidence D L (*fig.* 7.) is to D B, the distance of the object from the tangent at the point of reflection C, as L M, the distance of the image from the centre, is to M P, the distance of the image from the tangent. Since $o = x$, and $x = m$, o will be equal to m, and, therefore, the right line C P bisecting the angle D C M, cuts the base D M into two parts, which are in the same proportion with the sides; consequently, D P : P M :: D C : C M; and if D F be drawn parallel to C M, u will be $= p$, and, as $u = y$, $p = y$, and D F = D C. Therefore, since D F (D C) : M C :: D L : M L, D L will be to M L :: D P : P M; and, therefore, D L : D P :: M L : P M. Hence, because D L > D P, and M L > P M; and, therefore, M L much greater than R M, the distance of the image from the centre is greater, but from the tangent less than half the semidiameter; and the image is nearer to the tangent than the centre.

Hence, also, the distance of the object from the tangent is greater than that of the image, and, consequently, the object is farther distant from the speculum than the image.

3. If the arc B D (*fig.* 8.) intercepted between the point of incidence D, and the cathetus A B; or the angle C, formed in the centre of the mirror by the cathetus of incidence A C, and that of obliquation F C, be double the angle of incidence, the image B will appear on the surface of the speculum.

4. If the arc intercepted between the point of incidence and the cathetus; or the angle C, formed in the centre of the mirror by the cathetus of incidence, and the cathetus of obliquation, be more than double the angle of incidence, the image will be without the mirror.

5. If the arc intercepted between the point of incidence, and the cathetus; or the angle, formed in the centre of the mirror by the cathetus of incidence, and that of obliquation, be less than double the angle of incidence, the image will appear within the speculum.

6. In a convex mirror, a remoter point A (*fig.* 9.) is reflected from a point F, nearer the eye O, than any nearer point B in the same cathetus of incidence.

Hence, if the point of the object A be reflected from the point of the mirror F, and the point of the object B from the point of the mirror E; all the intermediate points between A and B will be reflected from the intermediate points of the speculum between F and E; and, consequently, F E will be the line that reflects A B.

Hence, also, a point of the cathetus B seems at a greater distance C*b* from the centre C, than a more remote one, A.

7. A nearer point B (*fig.* 10.) not in the same cathetus with a remoter H, is reflected to the eye O, from a nearer point of the speculum, than the remoter H.

Hence, if the point of an object A be reflected from the point of a mirror C, and the point of the object B, from the point of the speculum D, all upon the same point O; all the intermediate points between A and B will be reflected from all the intermediate points between C and D. Consequently, the image F G of the object B A is contained between the cathetus B E and A E.

8. In a spherical convex mirror the image is less than the object.

And hence the use of such mirrors in the art of painting, where objects are to be represented less than the life.

9. In a convex mirror, the more remote the object the less its image; and, again, the smaller the mirror the less the image.

10. In a convex mirror, the right hand is turned to the left, and the left to the right; and magnitudes perpendicular to the mirror appear inverted.

11. The image of a right line, perpendicular to the mirror, is a right line; but that of a right line either oblique to the mirror, or parallel to it, is convex.

12. Rays reflected from a convex mirror diverge more than if reflected from a plane mirror.

Hence light, by being reflected from a spherical mirror, is weakened; and, consequently, the effects of reflected light are weaker than those of direct. Hence, also, myopes see remote objects more distinctly in a convex mirror, than they do directly.

Rays reflected from a convex mirror of a smaller sphere diverge more than those reflected from a larger. Consequently, the sight is more weakened, and its effects are less considerable in the former case than in the latter.

Mirrors, *Concave*, are those whose surface is concave. These are generally made of a mixed metal.

Note, by *concave*, authors commonly mean *spherically concave*.

Mirrors, *Manner of preparing or making Concave*. First, a mould is to be provided for casting them. In order to this, take clay well dried, pulverize and sift it; mix it up with water, and then strain or filter it; with this work up horse-dung, and hair shred small, till the mass be sufficiently tough; to which, on occasion, may be added charcoal-dust, or brick-dust, well sifted.

Two coarse moulds are then prepared of a gritty stone, the one concave the other convex; which are to be ground by one another with wet sand between, till such time as the one perfectly fits the other. By this means, a perfect spherical figure is acquired.

The mass, prepared before, is now to be extended on a table, by means of a wooden roller, till it be of a thickness proper for the mirror; and then being strewed with brick-dust to prevent its sticking, it is laid over the convex mould, and so gets the figure of the mirror. When this is dry, it is covered with another lay of the same mass; which once dried, both the covers, or segments of the clay, are taken off. The innermost of the two being laid aside, the stone mould is anointed with a pigment prepared of chalk and milk, and the outer cover again put over it.

Lastly, the joining being covered over with the same clay of which the cover is formed, the whole mould is bound together with an iron wire, and two holes are cut through the cover, the one for the melted matter of the mirror to be poured through, the other for the air to escape at, to prevent the mirror's being spoiled with bubbles.

The mould being thus prepared, eight parts of copper, one

one of English tin, and five of bismuth, are melted together; a little of the mixture is taken out with a ladle, and if it be too red, when cold, more tin is put in; if too white, more copper; the mass is then poured into the mould before prepared, and so assumes the figure of a mirror.

Some with ten parts of copper mix four of English tin, and a little antimony and sal ammoniac, stirring the mass about as long as any fumes arise in it: others have other compositions, many of which are described by Schottus and Zahnius.

The mirror, being thus cast, is cemented to a wooden frame, and thus worked to and fro over the convex stone mould, first with water and sand, and, lastly, without sand till it be fit for polishing; the stone mould is then covered with paper, and that is smeared over with tripoli dust, and calx of tin, over which the mirror is worked to and fro till it has got a perfect polish. And in the same manner are glass mirrors polished, excepting that the convex surface is there worked in the concave mould When the mirrors are very large, they are fixed on a table, and first ground with a gritty stone, then with pumice, then with fine sand, by means of a glass cemented to a wooden frame; and, lastly, they are rubbed with calx of tin, and tripoli dust, on a wet leather.

For concave mirrors of glass, the mould is usually made of alabaster; the rest is as in metal mirrors. See SPECULUM, GRINDING, and POLISHING.

MIRRORS, *Laws and Phenomena of Concave*. 1. If a ray, as K I (*fig.* 11.), fall on a concave mirror E I, under an inclination of 60 degrees, and parallel to the axis A B, the reflected ray I B will concur with the axis A B, in the pole of the glass B. Since $m = 60°$, n also will be $= 60°$, and because K I is parallel to the axis A B, $i = 60°$, and $u = 60°$; therefore C B = C I, the radius. Consequently the point B, in which the reflected ray I B concurs with the axis, is in the surface of the speculum. If the inclination of the incident ray be less than 60 degrees, as that of E H, the reflected ray E F will concur with the axis at the distance B F, which is less than a fourth part of the diameter. Since $o = x$, and, on account of the parallels H E and A B, $o = y$, we shall have $x = y$, and, therefore, E F = F C; but C F + E F > E C, and C E = C B; therefore C F + E F > C B: consequently C F > F B; *i. e.* F B is less than half the radius C B, or a fourth part of the diameter. And, universally, the distance of the point F, in which the ray H E concurs with the axis, from the centre C, is to half the radius C D in the ratio of the whole sine, to the cosine of inclination. For by the last demonstration it appears, that F E is = F C; therefore if from F a perpendicular F D be let fall on E C, L C will be $= \frac{1}{2}$ C E; but if C F be taken for the whole sine, C D will be the sine of the angle D F C, or the cosine of the angle D C F; *i. e.* of the inclination D E H; and, therefore, C F is to C D as the whole sine is to the cosine of the inclination.

Hence it is inferred, by calculation, that in a concave spherical mirror, whose breadth subtends an angle of six degrees, parallel rays meet, after reflection, in a part of the axis less than the one thousand four hundred fifty-seventh part of the radius; if the breadth of the concave mirror be 12, 18, 24, 30, 36 degrees; the part of the axis in which the parallel rays meet, after reflection, is less than $\frac{1}{363}$, $\frac{1}{162}$, $\frac{1}{59}$, $\frac{1}{58}$, $\frac{1}{38}$, the radius.

And on this principle it is, that burning glasses are formed.

For since the rays diffused through the whole surface of the concave mirror, after reflection, are contracted into a very small compass, the light and heat of the parallel rays must be prodigiously increased thereby; *viz.* in a duplicate ratio of the breadth of the mirror, and the diameter of the circle in which all the rays are collected; and since the sun's rays are, as to any purposes on earth, parallel, it is no wonder that concave mirrors should burn with so much violence.

From this same principle is likewise deduced a method of representing the images of objects in a dark room; which see under CAMERA *obscura*.

2. A lucid body being placed in the focus F, of a concave mirror E I (*fig.* 12.), the rays, after reflection, become parallel. For parallel rays are by reflection united in a focus; but if the luminous body be in the focus F, that which was before the reflected ray E F will be now the incident ray, and *vice versâ*; therefore the reflected ray E H will now become parallel to the axis A B, and all the reflected rays parallel to one another.

Hence an intense light may be projected to a vast distance, by a lighted candle, &c. placed in the focus of a concave mirror.

Hence also, if the parallel rays be received by another concave mirror, they will again concur in its focus, and burn.

Zahnius mentions an experiment of this kind made at Vienna, where two concave mirrors, the one six, the other three feet diameter, being placed about twenty-four feet apart, with a live coal in the focus of the one, and a match and tinder in the other, the rays of the coal lighted the tinder.

3. If a lucid body be placed between the focus F (*fig.* 13.) and the mirror H B C, the rays, after reflection, will diverge from the axis B A. If the lucid body were in F, the reflected ray C E would be parallel to the axis A B, and, therefore, it would constantly preserve the same distance from the axis. But since D C G > F C G, K C G will be > E C G; and, therefore, C K will fall beyond C E, and cannot be parallel to the axis, but must continually diverge from the axis, the distance from it increasing: whence it follows, that light is weakened by reflection.

4. If a lucid body be placed between the focus F, and the centre G, as in I, the rays, after reflection, will meet in the axis beyond the centre. In this case I H G < F H G, and, therefore, G H A < G H L; consequently, the reflected ray H A recedes from the parallel towards the axis, and its distance from the axis will be continually diminished, till at length it concurs with the axis. But if the lucid body be placed in A, that which was before the reflected ray A H will now become the incident ray, and *vice versâ*. If, therefore, the lucid body be placed beyond the centre G, the rays after reflection will concur with the axis between the focus F and centre G.

Hence, if a candle be placed in I, the image will appear in A; if it be placed in A, its image will be in I: in the intermediate points between I and A, the section of light will be a circle; and that so much the greater, as it is nearer the point of concourse.

5. If a luminous body be placed in the centre of the mirror, all the rays will be reflected back upon themselves; for as they fall perpendicularly on the speculum, they will be reflected into themselves.

Hence, if the eye be placed in the centre of a concave mirror, it will see nothing but itself, and that confusedly, through the whole mirror.

6 If a ray falling from the point of the cathetus *b* (*fig.* 14.) on the convex mirror *b* F, be, together with its reflex I F, continued within the concavity of the mirror, F H will be the incident ray from the point of the cathetus H, and F O its reflex. For *b* F E = I F M; but *b* F E = M

= M F O, and I F M = E F H; therefore M F O = E F H; and, consequently, if H F be taken for the incident ray from the point H, F O will be the reflected ray.

Hence, since the point of the cathetus H is the image of the point *b* in the convex mirror, but the point *b* the image of H in the concave; if the image of an object, reflected by a convex speculum, be seen by a reflection made in its concavity, it will appear like the object itself.

And since the image of an infinite cathetus is less in a convex glass than one-fourth of its diameter; a portion of the cathetus, less than a fourth part of the diameter, may appear of any magnitude required in a concave one. A point, therefore, distant from a concave speculum less than one-fourth of the diameter, must appear behind the mirror at any distance, how great soever.

Since the image of any object, how broad soever, is contained in a convex speculum, between the two lines of incidence of its extreme points; if an object be placed between the two lines, at a distance less than one-fourth of its diameter, the breadth of the image, how great soever, may all appear.

Since then the image of an object included between two lines, at a distance less than one-fourth of the diameter, may exceed the just height and breadth of the object; nay, may be made of any magnitude, how big soever; objects placed between the focus and mirror must appear of enormous magnitudes in concave mirrors; the image being so much the greater in the concave mirror, as it is less in the convex.

In a convex mirror, the image of a remote object appears nearer the centre than that of a nearer object: therefore, in a concave mirror, the image of an object remote from the mirror appears at a greater distance than that of a nearer object, provided the distance of the object from the centre be less than a fourth part of the diameter.

In a convex speculum, the image of a remote object is less than that of a near one: therefore, in a concave one, the image of an object placed between the focus and the mirror, is nearer the focus than the speculum.

The image, therefore, of an object receding continually from a concave speculum, becomes continually greater, provided it do not recede beyond the focus, where it becomes confused; and as it approaches, it grows continually less. In a convex speculum, if the sphere, of which it is a segment, be smaller, the image is smaller than in another of a larger sphere: therefore in a concave, if the sphere, of which it is a segment, be smaller, the image will be larger than in another whose sphere is larger: whence concave mirrors, if they be segments of very small spheres, will do the office of microscopes.

7. If an object A B (*fig.* 15.) be placed between a concave mirror and its focus, its image will appear behind the mirror in an inverted situation. Let A B be the length of the object: since the point A is seen in the cathetus C *a*, and the point B in the cathetus C *b*, the higher point is seen in the higher place *a*, and the lower in the lower *b*; or the object appears behind the mirror in an erect situation. But if A B represent the breadth of the object, it appears in the same manner that the part to the right corresponds with the right, and the left to the left, both of the object and image. However, in direct vision the right hand part of an object corresponds to the left of the spectator, and the left to the right; and, therefore, in a concave speculum, the parts to the left hand of an object between the focus and speculum appear to the right, and the right to the left.

8. If an object A B (*fig* 16.) be placed between the focus and the centre, its image E F will appear inverted, and in the open air, beyond the centre, the eye being placed beyond the centre. For the rays, by which the point A is reflected, concur in the cathetus G F, beyond the centre C in F, and those by which the point B is reflected, concur in the cathetus D F, beyond the centre C in E; therefore the point B radiates on the eye placed beyond E F as from E, and the point A as from F; consequently B is seen in E, and A in F, and the image of the object is seen beyond the centre in an inverted position. 9. If an object E F be placed beyond the centre C, and the eye likewise beyond the centre, the image will appear inverted in the open air, between the centre and the focus. Hence, the inverted images of objects placed beyond the centre, are reflected by a concave mirror, erect; and may be received on a paper applied between the centre and the focus, especially if the room be dark; if the object E F be farther distant from the centre than the focus, the image will be less than the object; because A C is less than E C, and, therefore, A B < E F.

On this principle, concave mirrors, especially those which are segments of large spheres, and are capable of reflecting entire objects, exhibit many pleasing phenomena. Thus, if a man flourish his sword against the mirror, another comes out of it, and meets him with the same motions; and the image of his head coming out of the mirror, if he strike with his real sword, the imaginary sword will strike his real head. If he stretch out his hand, another hand will be stretched out of the mirror, and meet it at a great distance in the open air, &c. And on the same principle are constructed catoptric cistulæ, which, when looked into, exhibit images much bigger than the chest. See CATOPTRIC *cistula*.

10. The image of a right line, perpendicular to a concave mirror, is a right line; but all oblique or parallel lines are concave. For since every point of a line perpendicular to the speculum is in the cathetus of incidence, its image will of course be a right line. But if A B (*fig.* 15.) be parallel, or oblique to the speculum, and C F be drawn from the centre C perpendicular to A B, C A will be greater than C D; and, therefore, as C F = C E, F D > A E; consequently the point D will appear farther behind the speculum than A. Therefore, since *c* is farther distant from D, than *a* from A, and *b* from B, the image *a c b* will appear concave.

MIRRORS, *Cylindrical, Conical, Parabolical,* and *Elliptical,* or specula, are those terminated by a surface respectively cylindrical, conical, parabolical, and sphercidical.

To prepare, or make, cylindrical, conical, parabolical, elliptical, and hyperbolical Mirrors.—For the *cylindrical* and *conical* sort, if they are to be of glass, the method of preparing them is the same as that already laid down for convex mirrors.

If of metal, they are to be made after the manner of concave mirrors, only that the clay moulds there described require other wooden ones of the figure of the mirror.

For *elliptical, parabolical,* and *hyperbolical* mirrors, the mould is to be thus prepared. On a wooden or brazen plane or table, describe the figure of an ellipsis, A B (*fig.* 17.) a parabola, or an hyperbola, C D (*fig.* 18.) after the manner taught under those heads; which done, cut out the figure from the plane with all the accuracy imaginable.

To the elliptic figure fit an axis, as E F, with two fulcra to sustain it, &c. and a handle to move it; lay a quantity of the clay, above described, under it; and turn about the axis by the handle, till the plane A B hath turned, or impressed the elliptical figure exactly upon it.

The axis of the parabolical or hyperbolical figure C D, is to be fixed at the vertex E in such a manner as that it may

may always remain erect; this is to be turned about as above, till it hath given its own figure to the clay applied about it. The part of the mould, thus formed, is to be dried, and either smeared over with fat, or sprinkled with brickdust; then a convex mould is to be made, by putting a quantity of the same clay into the cavity thus formed. This latter is called the *male*, as the former the *female* mould. The male mould, being well dried, is to be applied within the female, in such a manner, as only to leave the intended thickness of the mirror between them. The rest as for concave mirrors.

These mirrors are not made without the utmost difficulty; because, if the moulds be ever so just, the figure of the mirror is apt to be damaged in the grinding. See SPECULUM.

MIRRORS. *Phenomena, or Properties of Cylindrical.* 1. The dimensions of objects corresponding lengthwise to the mirror are not much changed; but those corresponding breadthwise have their figures altered, and their dimensions lessened so much the more, as they are farther from the mirror; whence arises a very great distortion.

2. If the plane of reflection cut the cylindric mirror through the axis, the reflection is performed in the same manner as in a plane mirror; if it cut it parallel to the base, the reflection happens in the same manner as in a spherical mirror; if, lastly, it cut it obliquely, or be oblique to its base, the reflection is the same as in an elliptical mirror. Hence, as the plane of reflection never passes through the axis of the mirror, except when the eye and objective line are in the same plane; nor parallel to the base, except when the radiant point and the eye are at the same height, the reflection, in a cylindrical mirror, is usually the same as in an elliptical one.

3. If a hollow cylindrical mirror be opposed directly to the sun, instead of a focus of a point, the rays will be reflected into a lucid line, parallel to its axis, at a distance somewhat less than a fourth part of its diameter.

Hence arises a method of drawing anamorphoses, *i.e.* wild, deformed figures, on a plane, which appear beautiful and well proportioned, when viewed in a cylindrical mirror.

MIRRORS, *as for Elliptic, Parabolic, Conic*, and *Pyramidal*, we are not much acquainted with their properties: only that in the first, if a ray strike on it from one of its focuses, it is reflected into the other; so that a lighted candle being placed in one, its light will be collected in the other. That the second, inasmuch as all the rays they reflect meet in one point, make the best burning-glasses of all others.

And, lastly, that wild, irregular figures, may be so drawn on a plane, as that, the eye being placed over the axis of the two last, they shall appear beautiful, and well proportioned. (See ANAMORPHOSIS.) For further particulars respecting the theory, materials, construction, and use of mirrors, see GLASS, GRINDING, LENS, MICROSCOPE, SPECULUM, and TELESCOPE.

MIRSERAI, in *Geography*, a town of Persia, in Khorasan; 12 miles W. of Sebsvar.

MIRZAGUNGE, a town of Hindoostan, in Bengal; 27 miles S.S.E. of Mahmudpour.

MIRZAPOUR, a town of Hindoostan, in Bengal; 75 miles S.S.E. of Mahmudpour.—Also, a town of Hindoostan, in Bengal; 12 miles S.W. of Kishenagur.—Also, a town of Hindoostan, in Oude; 33 miles N.E. of Kairabad.—Also, a town of Hindoostan, in Allahabad; 41 miles S.E. of Allahabad. N. lat. 25° 10′. E. long. 82° 49′.

MIRZIN, or WOLCIN, a town of Moravia, in the circle of Iglau; 12 miles E. of Iglau.

MIS, a particle prefixed to divers words, particularly law-terms; denoting some default or defect. As, in *misprision; misdicere, to scandalize one; misdocere, to teach amiss*, &c.

MISA, in *Geography*, a river of Naples, which runs into the Adriatic, N. lat. 43° 43′. E. long. 13° 12′.

MISAGNO, a town of Naples, in the province of Otranto; seven miles S.W. of Brindisi.

MISANDRA, in *Botany*, Juss. 405, one of Commerson's fanciful names, the application of which is not very clear to us. It seems to imply that he was displeased at meeting every where with a superabundance of the male plants of this kind, in the straits of Magellan, and only once with the females, so that he was long unable to judge of the genus; at least this appears to be the conjecture of Jussieu. See GUNNERA.

MISANI, in *Geography*, a town in the island of Corsica; six miles W. of Cervione.

MISANTHROPY, μισανθρωπια, formed of μισος, *hatred*, and ανθρωπος, *a man*, a general dislike or aversion to man, and mankind. In which sense it stands opposed to *philanthropy*, or the love of mankind.

MISAPA, in *Geography*, a river of Mexico, which runs into the gulf of Mexico, N. lat. 18° 12′.

MISARA, a town of Egypt, on the left bank of the Nile; 12 miles S. of Melaui.

MISAVENTURE, or MISADVENTURE, *Homicide by*, in *Law*. See HOMICIDE.

In the case of misadventure, the law presumes negligence, or at least a want of sufficient caution in him who was so unfortunate as to commit it; who, therefore, is not altogether faultless. The penalty inflicted by our laws is said by sir Edward Coke to have been anciently no less than death; though others affirm, with greater reason, that it consisted in a forfeiture, as some say, of all the goods and chattels; according to others, of only part of them, by way of fine or weregild; which was probably disposed of, as in France, for pious uses, or for the benefit of the soul of the deceased. However, the delinquent has now, and has had as early as our records will reach, a pardon, and writ of restitution of his goods as a matter of course and right, only paying for suing out the same; and, to prevent this expence, in cases where the death has notoriously happened by misadventure, or in self-defence, the judges will usually permit, if not direct, a general verdict of acquittal. See HOMICIDE.

Staundford distinguishes between *aventure* and *misaventure*. The first he makes to be mere chance: as if a man, being upon or near the water, be taken with some sudden sickness, and so fall in, and be drowned; or into the fire, and be burnt.

Misaventure, according to him, is when a man comes to his death by some outward violence; as the fall of a tree, the running of a cart-wheel, the stroke of a horse, or the like.

MISCANELLO, in *Geography*, a town of Naples, in Basilicata; 26 miles S.E. of Potenza.

MISCARRIAGE, in *Midwifery*, the birth, or exclusion of a fœtus from the womb before it has attained its maturity.

By some writers, the word miscarriage is confined to deliveries, or births happening before the end of the sixth or seventh month, or before the child has acquired so much strength as to give it a chance of living. Children born in the eighth or early in the ninth month, are only said to have come before their time. (See ABORTION, and CONCEPTION.) The failure in an attempt to perform any thing is also called a miscarriage.

MISCELLANEÆ, in *Botany*, a name given by Linnæus to the 54th of his Natural Orders, and which well expreffes the heterogeneous nature of that order, as it ftands at the end of his *Genera Plantarum*, where fuch various genera are brought together, that his leading idea in this affemblage can hardly be traced. They ftand under eight heads, as follows.

1. *Refeda, Datifca.*
2. *Poterium, Sanguiforba.*
3. *Piftia, Lemna.*
4. *Coriaria;* and *Empetrum* with a mark of doubt.
5. *Achyranthes, Celofia, Amaranthus, Irefine, Gomphrena, Phytolacca*
6. *Nymphæa, Sarracenia.*
7. *Cedrela, Swietenia.*
8. *Telephium.*

In the *Prælectiones in Ord. Nat. Plantarum*, publifhed from the notes of Gifeke and Fabricius, p. 594, this catalogue is much diminifhed, and the 54th order confifts of only the firft four of the above fections, without any remark or explanation.

The manufcript notes of Linnæus, to his own *Genera Plantarum*, here afford us fome affiftance. He has there referred the fecond fection of the above lift, very juftly, to his 35th order, *Senticofæ*, before *Agrimonia*.

The third fection he removes to ord. 15, *Inundatæ*, which is but a flight improvement.

The fifth goes with great propriety to his *Holeraceæ*, ord. 12th.

The fixth to his *Rhoeadeæ*, ord. 27th, with a queftion whether the genera here mentioned be not more akin to *Afarum* and his 11th order, *Sarmentaceæ ;* under which laft however he has expreffed a fufpicion that *Ariftolochia, Afarum* and *Cytinus* may rather belong, with *Nymphæa*, to the 27th.

The feventh fection he reduces to his *Trihilatæ*, ord. 23d, and *Telephium*, which alone makes the eighth, is removed to the *Holeraceæ*.

MISCELLANEÆ is alfo the name of an order of the *Cryptogamia*, according to Schreber, in his Gen. Pl. 753. Under it he comprehends *Equifetum, Lycopodium, Porella, Salvinia, Marfilea, Pilularia,* and *Ifoetes*. Thefe have little affinity, and the order can be confidered merely as a receptacle for what could not well be placed elfewhere, as its name feems to imply.

MISCHARON, in *Geography*, a town of Perfia, in the province of Irak ; 111 miles S.E. of Hamadan.

MISCHIEF, *Malicious*, or *Damage*, in *Law*, is a fpecies of injury to private property, which the law confiders as a public crime. This is fuch as is done, not *animo furandi*, or with an intent of gaining by another's lofs ; but either out of a fpirit of wanton cruelty, or diabolical revenge. Any damage arifing from this mifchievous difpofition, though only a trefpafs at common law, is now by a multitude of ftatutes made penal in the higheft degree. 22 Hen. VIII. c. 11. 43 Eliz. c. 13. 22 & 23 Car. II. c. 7. 4 & 5 W. & M. c. 23. 1 Ann. ftat. 2. c. 9. and 4 Geo. I. c. 12. 12 Ann. ftat. 2. c. 18. 1 Geo. I. c. 48. 6 Geo. I. c. 23. 9 Geo. I. c. 22. (See BLACK *Act*.) 6 Geo. II. c. 37. 10 Geo. II. c. 32. 28 Geo. II. c. 19. 6 Geo. III. c. 36. and 48. and 13 Geo. III. c. 33. 9 Geo. III. c. 29. 13 Geo. III. c. 38. See FELONY.

MISCHKA, in *Geography*, a river of Ruffia, in the country of the Coffacks, which runs into the Don, near Verchnei Tchirkovfkaia.

MISCHKIN, a town of Ruffia, in the government of Jaroflavl ; 60 miles W. of Jaroflavl. N. lat. 58° 42′. E. long. 40° 22′.

MISCHNA, or MISHNA, from שנה, *iteravit*, a part of the Jewifh Talmud.

The Mifchna contains the text ; and the Gemara, which is the fecond part of the Talmud, contains the commentaries ; fo that the Gemara is, as it were, a gloffary on the Mifchna.

The Mifchna confifts of various traditions of the Jews, and of explanations of feveral paffages of fcripture : thefe traditions, ferving as an explication of the written law, and fupplement to it, are faid to have been delivered to Mofes during the time of his abode on the Mount ; which he afterwards communicated to Aaron, Eleazer, and his fervant Jofhua. By thefe they were tranfmitted to the feventy elders, by them to the prophets, who communicated them to the men of the great fanhedrim, from whom the wife men of Jerufalem and Babylon received them. According to Prideaux's account, they paffed from Jeremiah to Baruch, from him to Ezra, and from Ezra to the men of the great fynagogue, the laft of whom was Simon the Juft ; who delivered them to Antigonus of Socho ; and from him they came down in regular fucceffion to Simeon, who took our Saviour in his arms ; Gamaliel, at whofe feet Paul was educated, and laft of all to Rabbi Judah the Holy, who committed them to writing in the Mifchna. But Dr. Prideaux rejecting this Jewifh fiction, obferves, that after the death of Simon the Juft, about two hundred and ninety-two years before Chrift, the Mifchnial doctors arofe, who, by their comments and conclufions, added to the number of thofe traditions, which had been received and allowed by Ezra, and the men of the great fynagogue ; fo that towards the middle of the fecond century, after Chrift, under the empire of Antoninus Pius, it was found neceffary to commit thefe traditions to writing ; more efpecially as their country had confiderably fuffered under Adrian, and many of their fchools had been diffolved, and their learned men cut off ; and, therefore, the ufual method of preferving their traditions had failed. Rabbi Judah, on this occafion, being rector of the fchool of Tiberias, and prefident of the fanhedrim in that place, undertook the work, and compiled it in fix books, each confifting of feveral tracts, which altogether make up the number of fixty-three. (Prid. Connect. vol. ii. p. 468, &c. ed. 9.) This learned author computes that the Mifchna was compofed about the 150th year of our Lord ; but Dr. Lightfoot fays, that Rabbi Judah compiled the Mifchna about the year of Chrift 190, in the latter end of the reign of Commodus ; or, as fome compute, in the year of Chrift 220. Dr. Lardner is of opinion that this work could not have been finifhed before the year 190, or later, and he thinks that it is placed foon enough at the year 180. (Collect. of Jewifh and Heathen Teftimonies, &c. vol. i. p. 178.) Others, however, apprehend, that the Mifchna was not committed to writing till near the middle of the fifth century, alleging that St. Auftin, who died in the year 430, fays exprefsly (Cont. Adverf. Leg. and Proph. lib. ii. c. 1.) that the Jewifh traditions were not in writing. And yet that it was written before 500 feems evident, becaufe in 548 Juftinian interdicted the ufe of it in the fynagogues. Kennicott's State of the Hebrew Text, vol. ii. p. 443.

Thus the book called the Mifchna was formed ; a book which the Jews have generally received with the greateft veneration. The original has been publifhed, with a Latin tranflation, by Surenhufius, with notes of his own, and others from the learned Maimonides, &c. in 6 vols. folio, Amfterd. A.D. 1698—1703. See TALMUD.

It is written in a much purer ftyle, and is not near fo full of dreams and vifions, as the Gemara.

MISCIANO, in *Geography*, a town of Naples, in the province of Otranto; 8 miles W.S.W. of Brindisi.

MISCO, or MISKO. See MIXCO.

MISCONTINUANCE, in *Law*, the same with discontinuance.

MISCOTHINS, in *Geography*, a small tribe of Indians who inhabit between lake Michigan and the Mississippi.

MISDEMEANOUR, or MISDEMESNOR, in *Law*, an offence, or fault, particularly when in the execution of an office. See CRIME.

High crimes and misdemeanours denote offences of a heinous nature, next to high treason.

MISE, a French term, literally denoting expence, or disbursement: it is used in our law-books in divers acceptations. Sometimes for the profits of lands; sometimes for taxes, or taillages; and sometimes for expences, or costs: as *pro misis & custagiis*, for costs and charges in the entries of judgments, &c.

Mise more peculiarly denotes an honorary gift, or customary present, with which the people of Wales used to salute every new king and prince of Wales, at their entrance upon the principality.

Anciently, the mise was given in cattle, wine, corn, &c. for the support of the prince's family; but when that dominion was annexed to the English crown, the gift was changed into money. The county of Flint paid two thousand marks, &c. for the mise.

The county of Chester also paid a mise or tribute of five thousand marks at the change of every owner of the said earldom, for enjoying the privilege of that palatinate. At Chester they have a mise-book, in which every town and village in the county is rated what to pay towards the mise.

Mise is also used in speaking of a writ of right. What in other actions is called an *issue*, in a writ of right is called a *mise* or *me*: so that *to join the mise upon the mere*, is as much as to say, to join issue on the mere right, *i. e.* to join upon this point, whether the tenant or demandant has the more right.

Yet even in a writ of right, if a collateral point be tried, it is there called an *issue*, not a *mise*. See ISSUE.

Mise is also sometimes used corruptly for *mease*, a messuage or tenement.

In some manors, a *mise* or *mease* place is taken for such a messuage or tenement as yields the lord an heriot at the death of the tenant.

MISELAR, in *Geography*, an island in the East Indian sea, of an irregular form, 18 miles long and five broad, near the W. coast of Sumatra. N. lat. 1° 28′. E. long. 97° 56′.

MISEN, MISSEN, or MIZEN, in a *Ship*, denotes either the mast, or sail of that name; but at sea, they always mean the sail when the word *mizen* is used.

This is the hindmost of the fixed sails of a ship, extended sometimes by a gaff, and sometimes by a yard, which crosses the mast obliquely; the fore-end reaching always down to the deck, and the after-end being peeked up as high above the middle of the yard, where it is attached to the mast. The figure of the misen is a trapezium, or parallelogram, one of whose corners is cut off by a diagonal, extended from one of its sides to the opposite corner, which becomes the peek of the misen. Some great ships require two misens; in which case that next the main-mast is called the *main-misen*, and that next the poop the *benaventure misen*.

The use of the misen is, to keep the ship close to a wind; wherefore if a ship is apt to gripe too much, they use no misen. But it is often used when a ship rides at anchor, to back her a-stern; so that she may not foul her anchor, on the turning of the tide; and sometimes a ship lies a-try with her misen only.

MISEN-*mast* is the mast upon which the misen and its top-sail and stay-sails are supported, besides other sails, which are set occasionally, as the driver, ring-tail, &c. See MAST.

MISEN, *Change the*, is an order to bring the misen-yard over to the other side of the mast. *Peek the misen, i. e.* put the misen right up and down the mast.

MISEN, *Set the*, at *Sea*, the word of command to fit the misen-sail right as it should stand. *Spell the misen, i. e.* let go the sheet, and peek it up.

MISEN-*Stay*, in a *Ship*. See STAY.

MISEN-*Yard*. See YARD.

MISENO, CAPE, in *Geography*, a cape on the N. side of the gulf of Naples. N. lat. 40° 48′. E. long. 13° 52′.

MISERE, a river of America, which runs into lake Superior, N. lat. 46° 14′. W. long. 89° 3′.

MISERERE, *have mercy*, the name, and first word of one of the penitential psalms; being that commonly given by the ordinary to such condemned malefactors as are allowed the benefit of the clergy: whence it is also called the *psalm of mercy*.

It is also the first word in the Latin translation of the 51st psalm, and has been elaborately set to music by all the great composers of the Romish church, from Palestrina to Jomelli and Haydn: but no miserere has been so celebrated as that composed by Gregorio Allegri, for the pontifical chapel at Rome, in 1629; which has continued to be solemnly and exquisitely performed there on Wednesday in Passion week, and on Good Friday. See ALLEGRI, JOMELLI, and Burney's Present State of Music in France and Italy.

MISERERE *Mei*, denotes a kind of colic, or disorder of the intestines, in which the excrements, instead of passing off the common way, are often thrown up by the mouth. The *miserere mei* is the same with what we otherwise call *volvulus*, and *iliac passion*.

MISERICORDE, CULTELLUM, in *Ancient Armour*, the name of the dagger, which was the constant companion of the sword, at least from the days of Edward I., and is mentioned in the statute of Winchester. Its appellation of misericorde is derived by Fauchet, the French antiquary, either from its being used to put persons out of their pain, who were irrecoverably wounded, or, from the sight of it causing those knights who were overthrown to cry out for quarter or mercy. After the invention of fire-arms, daggers were screwed into the muzzles of the muskets, to answer the present purpose of the bayonet.

MISERICORDIA, MERCY, in *Law*, an arbitrary amerciament, or punishment imposed on any person for an offence.

Where the plaintiff or defendant in any action is amerced, the entry is always *ideo in misericordia*.

It is thus called, according to Fitzherbert, because it ought to be but small, and less than the offence, according to the tenor of Magna Charta.

"Mulcta lenior sic dicta, quod lenissima imponitur misericordia; graviores enim mulctas fines vocant; atrocissimas, redemptiones." See FINE and REDEMPTION.

Hence, if a man be unreasonably amerced in a court not of record, as a court baron, &c. there is a writ called *moderata misericordia*, directed to the lord, or his bailiff, commanding them to take moderate amerciaments.

MISERICORDIA *communis*, is when a fine is set on the whole county, or hundred.

MISERICORDIA *in cibis & potu*, in our *Old Writers*, is used for any gratuitous portion of meat and drink, given to the religious

ligious in convents beyond their ordinary allowance. (Matt. Paris.) And in fome convents they had a ftated allowance of thefe over-commons upon extraordinary days, which were called *mifericordiæ regulares*.

MISERREPOUR, in *Geography*, a town of Hindooftan. in Dooab; 15 miles N.W. of Etayah.

MISERY, an ifle between Salem and Cape Ann, in Maffachufetts.

MISFEASANCE, in *Law*, a mifdeed or trefpafs. Whence alfo *misfeafor*, a trefpaffer.

MISFORTUNE. See CHANCE.

MISGUM, in *Ichthyology*, the name of a fifh of the anguilliform kind, but broader and flatter than the eel, and of much the fame fize from the head to the tail; it has five black lines, one on the back, two, which are fomewhat broader, in the middle of the fides, and two others, which are narrower lower down; thefe are all extended from the head to the tail; the intermediate fpaces, and the belly, are of a fomewhat blueifh-white, dotted with black fpots; the fins are alfo fpotted in the fame manner; the mouth is fmall and round like that of the lamprey, and is furrounded with beards, fix on the upper jaw, and four on the under; and there are two other very flender ones near the noftrils; the eyes are fmall; the gills four on a fide; and befide the back fin there are four, two near the gills, and two lower on the body. This is a common fifh about the German fhores, and is efteemed a very delicate one at the table; it lays its fpawn in March, and is in beft feafon for eating in January and February. It is caught principally in ftanding and muddy waters; and it is faid, that when out of water, it makes a fort of hiffing noife.

MISHNA. See MISCHNA.

MISIANO, in *Geography*, a town of Naples, in Calabria Ultra; 7 miles N. of Reggio.

MISILMARI, a town of Sicily, in the valley of Mazara; 6 miles S.S.E. of Palermo.

MISITRA, the ancient *Sparta*, a town of European Turkey, in the Morea, defended by a caftle on a rock, which is faid to be impregnable. The Chriftians have feveral churches, one of which is reckoned the moft beautiful in the world. The Jews have three fynagogues, and the Turks have a fuperb mofque and hofpital. This town is the fee of an archbifhop, and the refidence of a bey, an aga, and a waywode; and it contains 12,000 inhabitants. In 1770 it was taken by the Ruffians; 40 miles S.S.W. of Argos. N. lat. 37° 10′. E. long. 22° 25′.

MISKERING, MISKERRING. See ABISHERING.

MISKOTZ, in *Geography*, a town of Hungary; 30 miles W. of Tokay.

MISLAVA, a town of Hungary; 10 miles E. of Libetau.

MISLETOE. See MISTLETOE.

MISLIWECZEK, JOSEPH, in *Biography*, fon of a miller in Bohemia, not far from Prague, a twin, born in 1737: the brothers refembled each other fo much, that their father was frequently uncertain to which of them he was fpeaking. They were both brought up to the father's trade; but Jofeph in learning mufic at the common reading and writing fchool, as all Bohemian children do, difcovered uncommon genius and love for the art. And his father was fcarcely dead before he quitted the miller's trade, and went to Prague, where he ftudied mufic under the celebrated organift Segert with fuch fuccefs, that he fhortly compofed fix fymphonies, one each month, from January to June. Then, in 1763, he went to Venice, where he had leffons from Pifcette, and afterwards to Parma, where he compofed his firft opera, which fucceeded fo much, as to procure him a call to Naples, where the opera of "Belerofonte" fo eftablifhed his reputation in Italy, that in the next ten years he brought nine operas on the ftage; among which "Olimpiade," in 1778, was particularly admired, efpecially the air, "Si circa fi dice." Soon after the performance of Belerofonte, he went to Venice as a mafter, where he had been before only a fcholar, and now was as well received as elfewhere. Then he removed to Pavia, and thence to Munich in 1779, and returned to Naples a fecond time. About 1780, Fortune turned her back upon him: the opera of "Armida," which he fet for Milan, was performed but once, in which almoft every thing, except a bravura air for Marchefi, was *fifchiata* (hiffed). Thence he went to Rome, where he had been unfortunate before, and where he met with new difgrace in 1781; in which city, after compofing for different theatres of Italy 30 operas, befides oratorios, and inftrumental mufic of all kinds, he died, in 1782, in mortification and indigent circumftances.

MISLOWITZ, in *Geography*, a town of Silefia, in the lordfhip of Plefz, on the borders of Poland; 32 miles W. of Cracow. N. lat. 50° 13′. E. long. 19° 5′.

MISNIA. See MEISSEN.

MISNOMER, compounded of *mis*, which in compofition fignifies *amifs*, and *nomer*, *to name*, in *Law*, a wrong name, or the ufing of one name for another.

A mifnomer furnifhes one of the principal pleas in abatement.

MISOLOGIO, in *Geography*, a town of the Morea, in the pafhawite of Carnia, containing about 5000 inhabitants. It is fituated on a fwampy flat, fcarcely above the level of the fea. An extenfive fhallow reaches along the coaft for many miles, and is paled in for a meir, and kept in repair by the farmers of the fifhery. This fifhery was farmed in 1811 by forty perfons, who pay to the vizier Ali Pafhaw upwards of 3500*l.* fterling. In Mifologio one of the priefts teaches Greek, and the children, as in other parts of Greece, are taught writing, &c. by the parochial clergy. The inhabitants wear the Albanian drefs, and though they grievoufly complain of the taxes, they admit the juftice and vigour of Ali Pafhaw's government. The town has a fmall fortification about two miles diftant from the fhore. The articles exported from Mifologio are fimilar to thofe which are ufually fent from Patras and Lepanto. It has lately begun to fend wool to Sicily, which wool is low priced, but not fo inferior in quality as might be fuppofed from the rates at which it is fold.

MISPACH, a town of Bavaria, in the lordfhip of Upper Waldeck; 27 miles S.S.E. of Munich.

MISPRISION, derived from the old French *mefpris*, a *neglect* or *contempt*, in *Law*, fignifies a neglect or overfight, and is generally ufed to denote all fuch high offences as are under the degree of capital, but nearly bordering upon them.

Mifprifions are generally divided into two forts: negative, which confift in the concealment of fomething which ought to be revealed; and pofitive, which confift in the commiffion of fomething which ought not to be done.

MISPRISION *of Clerks*, is a neglect of clerks, in writing, or keeping records.

By the mifprifion of clerks, no procefs fhall be annulled, or difcontinued. And juftices of affize fhall amend the defaults of clerks mif-fpelling a fyllable, or letter, in writing.

MISPRISION *of Felony*, which is the concealment of a felony which a man knows, but never affented to, is punifhable, in a public officer, by ftat. Weftm. 1. 3 Ed. 1. c. 9. with imprifonment for a year and a day; in a common perfon ſon with impriſonment for a leſs diſcretionary time; and in both with fine and ranſom at the king's pleaſure, declared by the judges in his courts of juſtice. Juſtices of the Common Pleas have a power to aſſeſs any amerciaments upon perſons offending by miſpriſions, contempts, or neglects, for not doing, or miſdoing, any thing, in or concerning fines.

MISPRISION *of Treaſon*, is a negligence in not revealing treaſon, where a perſon knows it to be committed.

It is enacted by ſtat. 1 & 2 Ph. & Mar. c. 10 that a bare concealment of treaſon ſhall be only held a miſpriſion; which concealment becomes criminal, if the party appriſed of the treaſon does not, as ſoon as conveniently may be, reveal it to ſome judge of aſſize, or juſtice of the peace. (1 Hal. P. C. 372.) Beſides, the ſtatute 13 Eliz. c. 2. enacts, that thoſe who forge foreign coin, not current in this kingdom, their aiders, abettors, and procurers, ſhall all be guilty of miſpriſion of treaſon. The puniſhment of miſpriſion of treaſon is loſs of the profits of lands during life, forfeiture of goods, and impriſonment during life. 1 Hal. P. C. 374.

The miſpriſions already recited belong to the claſs of thoſe that are denominated negative. Miſpriſions, which are merely poſitive, are generally termed *contempts* or *high miſdemeſnors*. See CONTEMPT.

MISQUE POCONA, in *Geography*, a town of South America, in the viceroyalty of Buenos Ayres, and province of Santa Cruz de la Sierra; 100 miles S.S.W. of Santa Cruz.

MISQUI, a town of Peru; 60 miles N. of La Paz.

MISR *el Attiké*, a town of Egypt, on the Nile, S. of Cairo, to which it is a kind of ſuburb.

MISS, a river of Carinthia, which runs into the Drave; five miles E. of Lavamand.

MISSA. See MASS.

MISSA *Papæ Marcelli*, is the title of a celebrated maſs in *Muſic*, compoſed by Paleſtrina, and ſaid to have prevented muſic from being baniſhed the church. Concerning this production, it has been related by Antimo Liberati, in his famous letter to Ovidio Perſapegi, and after him, by Adami, Bernardi, and other muſical writers, that the pope and conclave having been offended and ſcandalized at the light and injudicious manner in which the maſs had been long ſet and performed, determined to baniſh muſic in parts entirely from the church; but that Paleſtrina, at the age of twenty-ſix, during the ſhort pontificate of Marcellus Cervinus, intreated his holineſs to ſuſpend the execution of his deſign till he had heard a maſs, compoſed in what, according to his ideas, was the true eccleſiaſtical ſtyle. His requeſt being granted, the compoſition, in ſix parts, was performed at Eaſter, 1555, before the pope and college of cardinals; who found it ſo grave, noble, elegant, learned, and pleaſing, that muſic was reſtored to favour, and again eſtabliſhed in the celebration of ſacred rites. This maſs was afterwards printed, and dedicated to the ſucceſſor of Marcellus, pope Paul IV., by whom Paleſtrina was appointed maeſtro di capella to the pontifical chapel.

The friends of choral muſic will doubtleſs be curious to have a faithful and minute account of a compoſition which had ſufficient power to preſerve their favourite art from diſgrace and excommunication; and having before us an accurate ſcore of it, which Signor Santarelli, the pope's maeſtro di capella, himſelf procured out of the archives of the Siſtine chapel, where it is ſtill performed, we can venture to aſſert, that it is the moſt ſimple of all Paleſtrina's works: no canon, inverted fugue, or complicated meaſures, have been attempted throughout the compoſition; the ſtyle is grave, the harmony pure, and by its facility the performer and hearer are equally exempted from trouble.

MISSAL, MISSALE, a maſs-book, containing the ſeveral maſſes to be uſed on the ſeveral days, feaſts, &c.

The Roman miſſal was firſt compiled by pope Gelaſius, and afterwards reduced into better order by pope Gregory the Great; who called it the *book of ſacraments*.

Each dioceſe, and each order of religious, have their particular miſſal, accommodated to the feſtivals of the province, or of the order.

MISSALAND, in *Geography*, a river of Africa, which riſes in Dar Fur, and after a courſe of nearly 500 miles loſes itſelf in the lake of Fittré.

MISSASSAGA ISLAND, an iſland that lies oppoſite to the mouth of the river Trent in Upper Canada, and at the ſame diſtance from the portage at the head of the bay of Quito.

MISSASSAGA *River*, a river of Upper Canada, which runs into lake Huron, between le Serpent and Theſſalon rivers, on the N. ſhore. See MESSASAGUES.

MISSEL BIRD, in *Ornithology*, the common Engliſh name of the larger ſpecies of thruſh, called alſo the *ſkrite*, and by authors the TURDUS *viſcivorus major*; which ſee. It is much larger than any other of the thruſh kind; its legs and feet are yellow; its head of a browniſh lead colour, and its back, tail, and rump of the ſame colour, with an admixture of yellow; but in the ſummer months it a little changes its colour, and becomes more grey, or of the colour of unripe pickled olives; its throat, breaſt, and belly, are all variegated with black ſpots; the middle of its belly whitiſh, and the upper part of its breaſt, and part of its ſides, and the under feathers of its tail, yellowiſh; its bill is ſhorter and thicker than that of other thruſhes, and of a duſky colour, except the baſe of the lower mandible, which is yellow. It uſually is ſeen on the top branches of tall oaks, elms, and other high trees, and ſings very ſweetly, and is the largeſt bird that has any melody in its note. It begins its ſong, ſitting on the ſummit of a high tree, very early in the ſpring; often with the new year, in blowing ſhowery weather, whence it is called in Hampſhire the ſtorm-cock; the note of anger or fear is very harſh, between a chatter and ſhriek. It remains the whole year with us, flies ſingly, except with its female, and drives all the leſſer ſpecies of thruſhes from it. It is the beſt of all the kinds for the table.

MISSELTOE. See MISTLETOE.

MISSEN-MAST, or MIZZEN-*Maſt*. See MISEN.

MISSEN-*Sail*. See MISEN.

MISSIGUINIPPI RIVER, in *Geography*, a river of Canada, which runs into the Saguenay, N. lat. 48° 22′. W. long. 71° 10′.

MISSILIA, among the Romans, a name given to largeſſes, thrown among the people on occaſion of games and ſhows, ſuch as ſmall gold or ſilver coins, ſweetmeats, and ſometimes animals, as ſheep, oxen, deer, &c. which were let looſe to be carried off by the people.

The word comes from *mittere*, *to throw*, or *let looſe*.

MISSIMA, in *Geography*, a town of Japan, in the iſland of Niphon.

MISSINABE LAKE, a lake of America, in Canada. N. lat. 48° 39′ 42″. W. long. 84° 2′ 42″.

MISSINABE *Houſe*, a ſtation belonging to the Hudſon's bay Company, ſituated on the E. ſide of Mooſe river, and eight miles from Miſſinabe lake.

MISSING WOOD, a phraſe uſed among *Bowlers*. See BOWLING.

MISSION, MISSIO, among the Romans, a term uſed to ſignify the emperor's ſending to reſcue a wounded gladiator from his antagoniſt. The *munerarii*, or perſons who exhibited

4 N 2

bited the games, and likewife the people, ufed to refcue a favourite gladiator. The manner of their fignifying this favour, was *pollice preffo*, or with the thumb hid in the palm of the hand. However the gladiator was only faved for that time; whereas by the *rudis* he had a free difcharge.

MISSION. See EMISSION, MANUMISSION, REMISSION, and TRANSMISSION.

MISSION, in *Theology*, denotes a power or commiffion to preach the gofpel. Jefus Chrift gave his difciples their miffion in thefe words, "Go, and teach all nations, &c."

The Romanifts reproach the Proteftants, that their minifters have no miffion; as not being authorifed in the exercife of their miniftry, either by an uninterrupted fucceffion from the apoftles, or by miracles, or by any extraordinary proof of a vocation.

Many among us deny any other miffion neceffary for the miniftry, than the talents neceffary to difcharge it.

MISSION is alfo ufed for an eftablifhment of people zealous for the glory of God, and the falvation of fouls; who go and preach the gofpel in remote countries and among infidels.

There are miffions in the Eaft as well as in the Weft Indies. Among the Romanifts, the religious orders of St. Dominic, St. Francis, St. Auguftine, and the Jefuits, have miffions in the Levant, America, &c.

The Jefuits have alfo miffions in China and all other parts of the globe, where they have been able to penetrate. The Mendicants abound in miffions.

There have been alfo feveral Proteftant miffions, for diffufing the light of Chriftianity through the benighted regions of Afia and America. Of this kind has been the Danifh miffion, planned by Frederic IV., in 1706. And the liberality of private benefactors in our own country has been alfo extended to the fupport of miffionaries among the Indians in America, &c.

MISSION is alfo the name of a congregation of priefts and laymen, inftituted by Vincent de Paul, and confirmed, in 1632, by pope Urban VIII., under the title of "Priefts of the Congregation of the Miffion."

Thefe profefs to make it their whole bufinefs to affift the poor people in the country; and to this purpofe they oblige themfelves never to preach, or adminifter any of the facraments, in any town where there is an archbifhop, bifhop, or provincial refiding.

The priefts of the miffion were alfo intrufted with the direction and government of a female order, called "Virgins of Love, or Daughters of Charity," whofe office it was to adminifter affiftance and relief to indigent perfons, who were confined to their beds by ficknefs and infirmity. This order was founded by a noble virgin, whofe name was Louifa le Gras, and received, in the year 1660, the approbation of pope Clement IX.

They are fettled in moft provinces of France, Italy, Germany, and in Poland. At Paris they have a feminary, which they call the *Foreign Miffion*, where youth are bred up, and qualified for miffions abroad.

MISSIONARY, an ecclefiaftic who devotes himfelf and his labours to fome miffion, either for the inftruction of the orthodox, the conviction of heretics, or the converfion of infidels.

MISSIQUASH RIVER, in *Geography*, a river which by its various windings, from its confluence with Beau-bafin at the head of Chignut channel, to its main fource, and from thence by a line due E. to the bay of Verte, in the ftraits of Northumberland, feparates the provinces of Nova Scotia and New Brunfwick.

MISSISIPPI, a large river of America, which, together with its eaftern branches, waters $\frac{5}{8}$ths of the United States, forms their weftern boundary, and feparates them from Louifiana. It rifes in White Bear lake, N. lat. 48° 15'. W. long. 98° 30', and in its courfe receives feveral ftreams both from the E. and W., the largeft of which are the Miffouri from the W., and the Illinois, Ohio, and Tenneffee from the E. The foil on both fides of this river, and in the vicinity of its tributary ftreams, is not inferior to any in North America. This river is navigable to St. Anthony's Falls, and, as fome fay, beyond them. Salt of excellent quality is produced from the falt-fprings or licks that are contiguous to it, and on its upper branches are great quantities of coal. An ifland of confiderable fize is formed by its mouths in the gulf of Mexico, between 29° and 30° N. lat. and 89° and 90° W. long.

MISSISIPPI *Territory*, a diftrict formed of the weftern part of the ftate of, and bounded N. by Tenneffee, W. by the Miffifippi river, S. to W. by Florida, E. by the Appalachicola and Flint rivers. The principal part of this country is inhabited by the Creek, Chactaw, Chickafaw, and Cherokee nations of Indians. It was erected into a territorial government in 1800, and divided into three counties, *viz.* Wafhington, including 1250 inhabitants, Pickering with 2940, and Adams with 4660. The total number is 8850, of which 3489 are flaves. Natches is the capital. It is watered by many fine rivers, and contains large tracts of the beft land in the United States.

MISSISSAGUIS, a tribe of Indians who inhabit the fhores of lake Ontario, and one of the moft numerous in this part of the country. The men are in general ftout, and moft excellent hunters and fifhers; but lefs warlike than any of the neighbouring nations. They are of a darker complexion than other Indians; fome of them being nearly as black as negroes. Both men and women, particularly the latter, are very dirty and flovenly in their appearance: the rancid greafe and fifh oil, with which the women daub their hair, necks, and faces, render them in a fummer's day extremely offenfive. Thefe Indians fupply the inhabitants of Kingfton, of Niagara, and of the different towns on the lake, with fifh and game, the value of which is eftimated by bottles of brandy and loaves of bread.

MISSIVE, fomething fent to another, from the Latin word *mitto*, *I fend*.

We fay miffive letters, or letters miffive, meaning letters fent from one to another.

In propriety letters miffive are letters of bufinefs, but not bufinefs of great concern; in contradiftinction from letters of gallantry, letters on points of learning, difpatches, &c. See LETTERS.

MISSON, MAXIMILIAN, in *Biography*, a well known French writer, was a counfellor of Paris at the time of the revocation of Nantes, which circumftance obliged him to quit his country and come over to England. In 1687, and the following year, he travelled to Italy with an Englifh gentleman, in the character of governor, and foon after his return he publifhed the fruits of his obfervations, in a work entitled "Nouveau Voyage d'Italie," in 3 vols. 12mo. Thefe travels were looked upon as a faithful and lively picture of the countries defcribed, but the Catholics were offended at the reprefentations given of the ceremonies and popular fuperftitions prevalent among them, which they charge with unfaithfulnefs and exaggeration. Miffon wrote likewife "Memoires d'un Voyageur en Angleterre;" and "Le Theatre facrè des Cevennes, ou Recit des Prodiges arrivès dans cette Partie du Languedoc, et des petits Prophètes." He died, at an advanced age, in London, in the year 1721. Moreri.

MISSOURI,

MISSOURI, in *Geography*, a river of North America, in Louisiana, which falls into the Mississippi from the westward, 18 miles below the mouth of the Illinois, and about 1160 miles from the Balize, or mouths of the Mississippi, in the gulf of Mexico. Hutchins says that it is navigable 1300 miles, and larger than the Mississippi.

MISSOURIS, the Indians who inhabit the banks of the above river, and who are said to have 1500 warriors.

MIST, a meteor, called also fog. See Fog and Meteorology.

The blueish mist which we sometimes see on our fields and pastures in a morning, though often innocent, yet has been in some places found to be the actual cause of murrain, and other fatal diseases among the horned cattle. Dr. Winklar gives, in the Philosophical Transactions, an account of a murrain affecting the cattle in Italy and other places, which was evidently seen to spread itself over the countries in form of a blue mist. Wherever this was perceived, the cattle were sure to come home sick: they appeared dull and heavy, and refused their food; and many of them would die in four-and-twenty hours. Upon dissection there were found large and corrupted spleens, sphacelous and corroded tongues; and in some places those people who were not careful of themselves in the management of their cattle, were infected and died as fast themselves. The principal cause of this disease seems to be the exhalation of some unwholesome steams from the earth; and it was observable, that there had been three earthquakes in Italy the year before it happened.

The method of cure which succeeded best, was this: as soon as any beast appeared to be sick, they examined the tongue, and if aphthæ or little blisters were found on it, they scraped it with a silver instrument made with sharp teeth at the sides, till it bled in all those parts where the aphthæ were; the blood was then wiped away with a cloth, and the whole tongue washed several times with vinegar and salt. After this the following medicine was given internally: take of soot, brimstone, gunpowder, and salt, of each equal parts: mix these in as much water as will make a mixture thin enough to be swallowed, and let a spoonful be given for a dose three or four times a day. The cattle which were in health had this medicine given them, as well as the sick; and the consequence was, that very few died in Swisserland, while almost all died in other places.

It was very remarkable that this contagion, on this occasion, seemed to travel slowly but regularly on: it came at the rate of about two German miles in twenty-four hours; this it kept regularly to during the whole time of its raging, and never appeared in very distant places at the same time.

The whole surface of the earth emitting these effluvia, no cattle escaped them in the course of their way, but those which were kept within doors at rack and manger, fell ill at the same time, and in the same manner with those in the open fields.

Dr. Slare was of opinion, that it was owing to certain insects, which could not fly faster than at the rate of two German miles a day; and that they travelled regularly, and spread the mischief where they passed; but there wanted some judicious persons, versed in these observations, to have examined both the state of the air and the beasts, on this occasion. Phil. Transf. N° 145.

MISTAKE Bay, in *Geography*, a large bay on the west side of the entrance of Davis's straits, and N. of Hudson's straits; from which it is separated by a peninsula of the N. main on the W. and Resolution island on the S.

MISTAKEN Bay, a bay on the N.W. coast of Tavai Poenammoo, so called by Capt. Cook in 1769; 25 miles S.W. of Cascade Point.

Mistaken, *Cape*, the S. point of the easternmost of the Hermit's islands, about three leagues E.N.E. from Cape Horn, at the extremity of South America.

MISTEK, a town of Moravia, in the circle of Prerau; 7 miles E.N.E. of Freyburg.

MISTELPACH, a town of Austria; 18 miles N. of Vienna.

MISTIC, or Mystic, a short river which falls into the N. side of Boston harbour, by a broad mouth on the E. side of the peninsula of Charlestown. It is navigable for sloops four miles to the town of Medford, and is crossed by two bridges, one at its mouth, and another a mile above it. The Middlesex canal connects this river with the Merrimack.

MISTISSINY, a lake of Canada. N. lat. 50° 40′. W. long 74°.

MISTLETOE, Misletoe, or *Misseltoe*, in *Botany*. See Viscum.

MISTRETTA, in *Geography*, a town of Sicily, in the valley of Demona; the see of a bishop; 64 miles W. of Messina. N. lat. 38° 55′. E. long. 14° 22′.

MISTY, a town of Asiatic Turkey, in Caramania; 50 miles S. of Yurcup.

MISUSER, in our *Old Writers*, an abuse of any liberty or benefit: as he shall make fine for his misuser. Old. Nat. Br. 149.

By misuser, a charter of a corporation may be forfeited; so also an office, &c.

MISWALDE, in *Geography*, a town of Prussia, in the province of Oberland; 18 miles S. of Elbing.

MISY, in *Natural History*, the name of a fossile substance, used very frequently by the ancients in medicine, and supposed to be one of their now lost medicines, but erroneously; it being still very common in the Turkish dominions, and not unfrequently found in the mines of Cremnitz in Hungary. It is a considerably firm substance, though of an irregular and seemingly not compact texture, and much resembles some of our gaudy marcasites; but that it wants their hardness and their weight, and is not inflammable.

It is at present no where put to any use. The ancients esteemed it of the same nature with the chalcitis, but that it possessed those virtues in a more remiss degree; they had it from Ægypt and Cyprus, and used it externally in hæmorrhages, and some cutaneous eruptions.

Misy, in *Botany*, a name given by Theophrastus, and all the old Greek writers, to a kind of truffle or subterranean mushroom, of a very delicate flavour. The truffles of Numidia, and some other parts of Africa, were always esteemed superior to those of any other part of the world. They are called *terfez*, *camaha*, or *kema*, by some later writers, and were brought to Rome, and so greatly esteemed, that no dish was ranked above them. These were called Lybian truffles by the Romans, and they seem to have been the same with the Cyrenean misy of the Greeks. It is to be observed, that the Greeks in general, in early times, were very little acquainted with the affairs of Africa; and all that they had from this part of the world, was said to come from Cyrene, some old cities of their forefathers being there, and keeping up a friendship and traffic with them. The *thyon*, a tree growing plentifully in almost all parts of Africa, and which is the same with the citrus of the Romans, was in this manner attributed to Cyrene, by the same Theophrastus. And thus, when speaking of truffles, he adds, that the Cyrenean misy surpassed all the other kinds in flavour; his words stand at large in Athenæus; and thence Pliny has taken his account,

account, which he closes in this manner: "The thing which they call misy, in the province of Cyrene, is of this kind; but it is more fleshy and of a finer taste and smell." This is the sense of Pliny, as the text stands in our copies; but it is probable that he translated Theophrastus better than they, at least as we know that what he says is not his own but taken from that author, we have a right to understand it in his way, and that is, that the roots of this Cyrenean misy have a delicate smell resembling that of meat, or flesh newly cut. Pliny, lib. xix. cap. 3.

It is very certain, that this Cyrenean misy of the old Greeks is the same thing with the delicate African truffle or terfez of Leo Africanus, and the moderns: and Pliny had read some of the ancients who were sensible of this, and had taken from them an account that the African truffles are the finest in the world; and yet did not perceive, that these African truffles were the same with the Cyrenean misy, which he immediately after mentions from Theophrastus.

MITCHEL DEAN, in *Geography*. See DEAN, *Michel.*

MITCHELLA, in *Botany*, named by Linnæus in honour of his friend and correspondent Dr. John Mitchell, a physician at Virginia, whose paper, describing thirty new genera of plants, is published in the *Ephemerides Naturæ Curiosorum*, v. 8, 187, preceded by a dissertation on the principles of systematic botany and zoology. This treatise was afterwards published separately at Nuremberg in 1769, about a year after its author's death. Linn. Gen. 55. Schreb. 73. Willd. Sp. Pl. v. 1. 617. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 246. Michaux Boreali-Amer. v. 1. 86. Juss. 208. Lamarck Illustr. t. 63. (Chamædaphne; Mitch. n. 27.)—Class and order, *Tetrandria Monogynia.* Nat. Ord. *Aggregatæ*, Linn. *Rubiaceæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, erect, four-toothed, permanent. *Cor.* of one petal, funnel-shaped; tube cylindrical; limb four-cleft, spreading, hairy within. *Stam.* Filaments four, thread-shaped, erect, between the segments of the corolla; anthers oblong, acute. *Pist.* Germen twin, inferior, orbiculate, common to two flowers; style thread-shaped, the length of the corolla; stigmas four, oblong. *Peric.* Berry divisible into two parts, globose, with two distinct crowns. *Seeds* four, compressed, callous.

Ess. Ch. Corolla of one petal, superior; two flowers on each germen. Stigmas four. Berry in two parts, with four seeds.

1. M. *repens.* Linn. Sp. Pl. 161. (Syringa baccifera; Pluk. Amalth. 198. t. 444. f. 2.)—Native of North America, and introduced at Kew in 1761, by Mr. John Bartram, where it flowers in June. *Stem* decumbent and creeping, slender. *Leaves* in pairs, on short stalks, ovate, pointed. *Flowers* terminal, two on each germen, as in several of the genus *Lonicera.*

MITCHELS, among *Builders*, are Purbeck stones, from fifteen inches square to two feet, squared and hewed ready for paving.

MITCHELSTOWN, in *Geography*, a post-town of the county of Cork, Ireland, situated on the river Funcheon. In it is a college, founded by a former earl of Kingston, for the support of twelve decayed gentlemen and twelve decayed gentlewomen, who have each 40*l. per annum*, and comfortable apartments; and a chaplain with 100*l. per annum*, with a house. A fine seat of the Kingston family adjoins the town. Near this town, at the foot of one of the Gattee mountains, is the cave of Skeheenrinky, which is described by Arthur Young in his Irish Tour, and preferred by him to the famous cave in the Peak of Derbyshire, as it was by lord Kingsborough to the Grot d'Aucel in Burgundy. Mitchelstown is 102 miles S.W. from Dublin, and about 24 from Cork, on the road from that city to Cashel. Carlisle. Young.

MITCHIGAMAS, a nation of Indians, who with the Piorias, inhabit near the settlements in the Illinois country.

MITE, in *Natural History*, the name of a small animal very well known, and found in old cheese, and in many other bodies, both recent and perishing. See ACARUS.

To the naked eye the mites in cheese appear like moving particles of dust, but the microscope discovers them to be perfect animals, having as regular a figure, and performing all the functions of life as perfectly as creatures that exceed them many times in bulk.

They are crustaceous animals, and are usually transparent; the principal parts of them are the head, the neck, and the body; the head is small in proportion to the body, and has a sharp snout, and a mouth that opens and shuts like a mole's; they have two small eyes, and are extremely quick-sighted; and when you have once touched them with a pin, you will easily perceive how cunningly they avoid a second touch.

They are of different sorts; for some of them have six legs, and others have eight: each leg has six joints surrounded with hairs, and two little claws at the extremity, with which it very nicely takes hold of any thing; the hinder part of the body is plump and bulky, and ends in an oval form, from which there issue out a few exceeding long hairs; other parts of the body and head are also beset with thin and long hairs.

The males and females are easily distinguished in these little animals. The females are oviparous, as the louse and spider, and from their eggs the young ones are hatched in their proper form, without having any change to undergo afterwards. They are, however, when first hatched, extremely minute; and, in their growing to their full size, they cast their skins several times.

These little creatures may be kept alive many months between two concave glasses, and applied to the microscope at pleasure. They are thus often seen *in coitu*, conjoined tail to tail; and this is performed by an incredible swift motion.

Their eggs, in warm weather, hatch in twelve or fourteen days; but, in winter, they are much longer; these eggs are so small, that a regular computation shews, that ninety millions of them are not so large as a common pigeon's egg. Baker's Microscope, p. 18.

Mites are very voracious animals; they not only prey upon cheese, but upon all sorts of dry flesh, fish, fruits, and seeds; and almost on all things which have some degree of moisture, without ever being wet; and they have often been seen to eat one another. Their manner of eating is by thrusting alternately one jaw forward and the other backward; and in this manner grinding their food; and after they have done feeding, they seem to chew the cud.

There are several lesser distinctions observable in the mites, which are found among different substances. Those in malt-dust and oat-meal are much nimbler than the cheese-mites, and have more and longer hairs. The mites among figs resemble beetles, and have two feelers at the snout, and two very long horns over them; these have only six legs, and are more sluggish than those in malt-dust. Those found among figs have also very long hairs, and those beset at certain distances with other smaller hairs; whence M. Leeuwenhoek conjectures that these longer and larger hairs are jointed at those places where the short ones are found.

There is a sort of wandering mites found wherever there is any thing that they can feed on; these are often found in form of a white dust, and are not suspected to be living creatures.

The

The mite is an animal very tenacious of life; it will live months without food; and M. Leeuwenhoek had one which lived eleven weeks on the point of a pin, on which he had fixed it for examining it by his microscope. Leeuwenhoek's Arcan. Nat. tom. iv. p. 368.

Mite, a small coin, formerly current; equal to about one-third part of a farthing.

Mite also denotes a small weight used by the moniers. It is equal to the twentieth part of a grain troy, and is divided into twenty-four droits, the droit into twenty periots, and the periot into twenty-four blanks.

MITELLA, in *Botany*, received its name from Tournefort, in allusion to the shape of the ripe seed-vessel, which, with its two pointed lobes, resembles a little mitre.—Linn. Gen. 223. Schreb. 301. Willd. Sp. Pl. v. 2. 659. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 73. Juss. 309. Tourn. t. 126. Michaux Boreali-Amer. v. 1. 270. Lamarck Illustr. t. 373. Gærtn. t. 44.—Class and order, *Decandria Digynia*. Nat. Ord. *Succulentæ*, Linn. *Saxifragæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cut half way down into five segments, bell-shaped, permanent. *Cor.* Petals five, in many capillary segments, inserted into the calyx, twice exceeding it in length. *Stam* Filaments ten, awl-shaped, inserted into the calyx, shorter than the corolla; anthers roundish. *Pist.* Germen superior, roundish, cloven; styles scarcely any; stigmas obtuse. *Peric.* Capsule ovate, of one cell, divided half way down into two flat, equal valves, recurved at their points. *Seeds* numerous.

Eff. Ch. Calyx five-cleft, inferior. Petals five, pinnatifid, inserted into the calyx. Capsule of one cell, with two equal valves.

1. M. *diphylla.* Two-leaved Mitella. Linn. Sp. Pl. 580. Lamarck, fig. 1. (Cortusa americana altera, floribus minutis fimbriatis; Menz. Pugill. t. 10.)—Leaves heart-shaped, slightly three-lobed, toothed. Stalk with two opposite leaves.—Native of North America. Easily cultivated in bog earth, in the shade, flowering in April and May. A delicate little perennial *herb*, about a span high, pale green, somewhat hairy. *Leaves* heart-shaped, acute, slightly lobed and toothed; the radical ones several, on longish footstalks. *Flower-stalk* solitary, erect, bearing a pair of sessile, opposite horizontal leaves about the middle, and terminating in a slender, upright, downy, rather viscid cluster, of minute white *flowers*, remarkable for their elegantly fringed feather-like petals. *Capsule* sometimes with three valves.

2. M. *cordifolia.* Heart-leaved Mitella. Willd. n. 2. Lamarck, fig. 3.—Leaves heart-shaped, with bristly teeth. Stalk nearly naked.—Supposed by Willdenow, we know not on what foundation, to be a native of the north of Asia. Michaux found it in Canada. This appears to differ from the former in having sharper bristle-pointed teeth to the *leaves*, and only one very small leaf, with a few scales, on the stalk. *Petals* in capillary segments. We have seen no specimen.

3. M. *nuda.* Naked-stalked Mitella. Linn. Sp. Pl. 580. Lamarck, fig. 2. (M. scapo nudo, petalis fimbriatis; Gmel. Sib. v. 4. 175. t. 63.)—Leaves kidney-shaped, wavy, fringed. Stalk naked.—Native of Siberia and North America, in woods. Miller is said to have cultivated this species in 1758, but we have never seen it in the gardens of the present day. It is smaller than the first species, with rounder, strongly bristly, *leaves*. *Stalk* three or four inches high, quite naked, bearing four or five *flowers*, the segments of whose petals are quite capillary.

4. M. *prostrata.* Prostrate Mitella. Michaux. n. 3.—"Root creeping. Stems prostrate. Leaves alternate, roundish-heart-shaped, sharpish, with slight obtuse lobes."—Native of the southern limits of Canada. *Michaux*

MITELLA, in *Surgery*, a scarf for suspending the arm.

MITGAING, in *Geography*, a town of Hindoostan, in the circar of Surgooja; 40 miles N. of Surgooja.

MITHRA, *Feasts of*, in *Antiquity*, were feasts celebrated among the Romans in honour of Mithra, Mithras, or the sun.

Mithras was an ancient god of the Persians, whom they worshipped, as Plutarch says, according to the laws of Zoroaster, invoking him as the mediator between Oromazes and Arimanius. Mithras was the sun, which was invoked as a divinity; to him they offered sacrifices, and addressed their prayers, and they had priests set apart for service; and they also worshipped fire as an emblem of the sun; but they had neither temples, statues, nor altars. This Mithras was not well known in Europe, until his worship was brought to Rome, which happened, according to Plutarch, in the time of the Piratic war, A. U. C. 687. It is from this epoch, and more especially from the time of the second and third century of the Christian era, that the worship and mysteries of this divinity were celebrated at Rome. That the Romans worshipped Mithras as the sun, is evident from an inscription dated in the third consulate of Trajan, or about the year of Christ 101. This is the dedication of an altar to the sun, under the name of *Mithra, deo Soli invicto Mithræ.* This epithet, invincible, is frequently given to the sun upon other monuments, and it denotes that luminary to be the first and lord of all the rest. But the worship of Mithras was not known in Egypt and Syria in the time of Origen, who died about the year of Christ 263: though it was common at Rome for more than a century before this time. The mysteries of Mithras were both impious and abominable, since human victims were offered on this occasion. The barbarous custom of sacrificing men was abolished by Adrian, but restored again by Commodus, as Lampridius informs us. This worship made great progress in succeeding ages. It was not only spread through Italy and Greece; but it appears from Socrates and Sozomen, that the Egyptians, and particularly the people of Alexandria, worshipped the same divinity. Mithras was also known in the island of Crete. He was also worshipped by the Gauls, as appears by a figure of this god found at Lyons. The worship of this divinity was not only extensive, but of long duration; for it was not destroyed when the emperors embraced Christianity. At length, this worship was proscribed at Rome in the year 378, by order of Gracchus, prefect of the prætorium. According to M. Freret, the feasts of Mithras were derived from Chaldea, where they had been instituted for celebrating the entrance of the sun into the sign Taurus.

Mithra is also a name of the sun in the mythology of the Hindoos. See Surya.

MITHRAX, in *Natural History*, the name given by Pliny and the ancients, to a gem found in Persia, which, when held up to the sun, shewed many colours. It was probably no other than the opal. Hence the barbarous writers of the middle ages seem to have taken their account of the mithridates.

MITHRIDATE, Mithridatium, in *Pharmacy*, an antidote or composition, in form of an electuary; serving either as a remedy, or a preservative against poisons. Mithridate was formerly one of the capital medicines in the apothecaries' shops, being composed of a vast number of drugs; among which are opium, myrrh, agaric, saffron, ginger, cinnamon, spikenard, frankincense, castor, pepper, gentian, &c.

It

It is accounted a cordial, opiate, sudorific, and alexipharmic. Matthiolus says, it is more effectual against poisons than Venice treacle, and much easier to be made.

It takes its name from its inventor, Mithridates, king of Pontus, who is reported to have so fortified his body against poisons, with antidotes and preservatives, that when he had a mind to dispatch himself, he could not find any poison that would take effect.

The receipt of it was found in his cabinet, written with his own hand, and was carried to Rome by Pompey. It was translated into verse by Damocrates, a famous physician, and hence called *Confectio Damocratis;* and was afterwards translated by Galen, from whom we have it. It has undergone considerable alterations since the time of its royal prescriber.

MITHRIDATE *Mustard.* See TREACLE *Mustard.*

MITHRIDATE, *Mustard Bastard,* is a species of *iberis.*

MITHRIDATEA, in *Botany,* received its name from Commerson, we presume in memory of Mithridates, who, from the celebrated hodge-podge, which he is reported to have invented, as a counter-poison, must have been conversant with herbs and their reputed properties at least. We can trace no reason for the application of the name to this particular plant.—Schreb 783. Willd. Sp. Pl. v. 1. 27. (Tambourissa; Sonnerat Ind. Or. v. 2. 237. Ambora; Juss. 401. Lamarck Illustr. t. 784.)—Class and order, *Monandria Monogynia.* Nat. Ord. *Scabridæ,* Linn. *Urticæ,* Juss.

Gen. Ch. *Common Receptacle* of one leaf, fleshy, bell-shaped, in four large, ovate, spreading segments; the upper surface covered with innumerable, minute, imbedded florets. *Perianth* scarcely any. *Cor.* none. *Stam.* Filament one, very short, erect; anther erect, channelled, embracing the style. *Pist.* Germen oval; style shorter than the stamen; stigma simple. *Peric* none. *Common Receptacle* enlarged, pulpy, turbinate, concave, its segments folded inward, lodging the seeds in its fleshy substance. *Seeds* solitary to each floret, oval.

Obs. Jussieu thinks the flowers are monoecious, the receptacles of the males being most deeply cut, and expanded, those of the females slightly perforated, by a cruciform incision, at the top. This seems to agree with our specimens from Commerson, but by no means with Sonnerat's description. Possibly the flowers may become monoecious occasionally, by the casual imperfection of their respective organs.

Ess. Ch. Common receptacle many-flowered, four-cleft. Calyx none. Corolla none. Seeds solitary, imbedded in the fleshy receptacle.

1. M. *quadrifida.* Ambora, Drum-tree, or Monkey-apple.—Gathered by Sonnerat in Madagascar, as well as in the isles of Bourbon and Mauritius. Commerson found it in the latter. The *wood* of this tree is light, white and pithy, as in *Ficus,* to which the genus is most nearly allied. *Leaves* on the young smooth branches, nearly opposite, stalked, elliptical, obtuse, entire, evergreen, very smooth, with a strong mid-rib, sending off numerous transverse veins; their size on young *trees* is a span in length, and above two inches in breadth; on old ones about one-third as much. *Flowers* in smooth clusters, from the older branches, or the trunk; their partial stalks about an inch long. *Receptacles,* before they expand, ovate, about the size of a filbert, somewhat roughish or scaly at the outside; when open the *male* ones, as they seem to us, spread about an inch and a half, displaying abundance of thick-set *stamens,* among which we can discern nothing else. The ripe *fruit* is two or three inches wide, of a depressed, roundish, unequal form, hollow, its pulpy substance, in which the *seeds* are vertically imbedded, as in *Dorstenia,* being about one-third of an inch thick. The pulpy coat, which envelopes the *seeds,* is said to be orange-coloured, and to be used for a dye, like the American Arnotto, *Bixa Orellana. Ambora* is the Madagascar name of this tree. The affinity of the genus to FICUS and DORSTENIA, (see those articles,) cannot be overlooked. The *foliage* however is smooth; but that is the case with some others of this natural order, though indeed with but very few. Jussieu says the tree discharges a milky fluid, which confirms its relationship to *Ficus;* and if monkies eat the fruit, as one of its names implies, it would certainly not prove poisonous to mankind, though, like many species of *Ficus,* it may be either tasteless or of a disagreeable flavour.

MITHRIDATES, in *Biography,* king of Pontus, surnamed "Eupator," and "The Great," was the son of Mithridates VI., the first king of that country who entered into an alliance with the Romans. At the death of his father, 123 B. C., he succeeded to the crown when he was only about 12 years of age. He was from a very early period of life accustomed to martial exercises, and the sports of the chase, by which he was enured to fatigues. In his mind were imprinted the characters of turbulence, ferocity, and suspicion, by which, particularly the latter, his life was preserved from several attempts made on him by those appointed to be his guardians. His mother had been appointed joint heir of the crown, but he very soon deprived her of power, and kept her in close confinement, in which she ended her days. When arrived at the age of manhood he took his own sister, Laodice, for a wife, which was the common practice of the eastern monarchs of that period. After the birth of a son he made a progress through all the neighbouring Asiatic states, with the view of observing their strength and policy. In this journey he spent three years, during which his queen attached herself to one of the lords of the court, and on his return she made an attempt to poison him. He drank the potion, but his constitution was proof against its baneful contents, and the discovery of her infidelity and wicked intentions was the occasion of her death, with that of all her accomplices.

Mithridates now entered upon his career of ambition: he overran the neighbouring kingdom of Paphlagonia, which he at length divided with his ally Nicomedes, the king of Bithynia, totally regardless of the remonstrances of the Romans, who had declared it a free state. He next reduced Galatia, though under the protection of Rome: after this he anxiously wished to make himself master of Cappadocia, then possessed by his brother-in-law, and friend Ariarathes, whom he caused to be privately assassinated, upon which the kingdom was seized by Nicomedes, who married the widow. Mithridates, however, under the pretence of securing the crown for his nephew, drove out Nicomedes, and seated the young prince upon the throne, whom he afterwards stabbed by the most scandalous treachery. The Cappadocian army, who were witnesses of the abominable deed, threw down their weapons, and suffered Mithridates to take possession of all the fortresses in the kingdom. He now placed on the throne a minor son of his own, under the guardianship of Gordius, who had been his wicked instrument in assassinating his brother-in-law. The jealousy of Nicomedes induced him to bring forward a pretended son of Ariarathes, who was sent to Rome to lay his complaints before the senate, and implore its assistance to seat him on the throne of his fathers. Mithridates, apprized of the fact, sent deputies to state to the senate the imposture, and in the conclusion both kings were commanded to relinquish their claims, and the crown of Cappadocia was conferred

ferred upon Ariobarzanes. This was but the commencement of the dispute, and the Roman commanders, according to their usual practice, endeavoured to excite hostilities among the Asiatic kings, that they might have a pretence to interfere in their contests. From the year 90 B. C. open war may be considered as prevailing between the Roman republic and Mithridates, which was extinguished only by the death of the latter. The early successes of Mithridates led him to aspire to the honour of being the instrument of freeing all Asia from the Roman yoke, and at first he seemed to overrun, in an uninterrupted career, all the countries in their alliance and possession, being every where received by the people as their deliverer. His great object now was to ingratiate himself with people of all classes and countries by several popular acts, such as restoring, without ransom, all the Asiatic prisoners, who had fallen into his hands. The free cities of Asia, won over by these specious acts of generosity, opened their gates to him, and took pleasure in demolishing all the monuments erected by the Romans. Mithridates, determined upon irreconcileable enmity to that people, and wishing to involve the Asiatics in the same principles, sent to the magistrates throughout the cities in which any Roman citizens had established themselves, directing, that on a certain day a general massacre should be perpetrated on all of Italian birth or origin, not excepting women and the youngest children. In this horrid massacre it was imagined, that at least 80,000 Roman citizens lost their lives; some accounts have indeed reckoned them at nearly double that number.

By this master stroke of bloody policy, for which his name must for ever be transmitted with infamy, Mithridates made himself master of the whole of Lesser Asia, and proceeded, without remorse or delay, to the conquest of the neighbouring islands, several of which he quickly reduced. At Cos he took possession of a large sum of money, which had been deposited there by the Asiatic Jews, and intended for the temple of Jerusalem. He next made an attempt upon Rhodes but was defeated, and incurred so much personal risque, that he ever afterwards felt an abhorrence of the sea. Archelaus, one of his generals, crossing over to Greece, made himself master of Athens, while his own son Ariarathes conquered Macedonia and Thrace. He was now at the summit of power, and is said to have received the homage of twenty-five different nations. His memory and talent for the acquisition of languages were so great that he could converse with the natives of all of them without the aid of an interpreter.

From this period we may date his decline; Sylla procured of his countrymen the chief command against Mithridates, and sailing to Greece recovered Athens, in the year 86 B. C. He afterwards defeated with great slaughter the troops of Archelaus at Chæronea, and by two other decisive victories he put an end to the war in Greece. Mithridates was pursued from place to place, till at length he was obliged to submit to conditions, at which the greatness of his mind revolted: these conditions were, that he should resign all his conquests, and confine himself within his paternal dominions of Pontus; that he should release all his captives without ransom; pay down a large sum of money; deliver up the greatest part of his fleet; and practise no hostilities against those who had revolted from him and taken part with the Romans. Although the king had acquiesced in these terms, yet it was with the secret determination to break them as soon as he should be sufficiently powerful for the purpose. A new war kindled about the year B. C. 74, in which the success of Mithridates was so great that he recovered the best part of Pontus, which had, in the early part of the contest, been wrested from him, Bithynia, Cappadocia, and Armenia Minor. At length Pompey, invested with great powers, was sent by the Romans to put an end to this long continued war, which he accomplished by destroying, or dispersing all the king's troops, except a body of cavalry with which he forced a passage. Mithridates fled into Armenia, whence he withdrew to Colchis, and thence to Scythia, between the Euxine and Caspian seas. Here he was so completely concealed that it was supposed he was dead, till he emerged from his retreat at the head of a considerable army, and made himself master of several important places. His success was but short-lived, and those even who were willing to submit to his power, had no confidence in his cause, but chose rather to join what they thought was the strongest party. He now adopted the design of marching into Europe, and exciting the Gauls in his cause, which created such discontents in the army, as to lead them to choose Pharnaces, the favourite son of Mithridates, as their king. Having in vain attempted to recal his son to the principles of duty, he attempted to destroy himself first by poison, and then by the sword, but in both he failed, and was at last dispatched, at his own request, by a Gallic mercenary. This was in the year B. C. 64, when the king had attained to the 71st year of his age. He was one of the most formidable enemies of the Roman republic, and the news of his death was received with the greatest joy and exultation. His body was delivered to Pompey, who, with the magnanimity of a generous enemy, bestowed upon it a most magnificent funeral. Mithridates was learned, and a patron of learning; he was particularly attached to medicine, and an electuary still bears his name. Plutarch. Univer. Hist.

MITHRIDATES, in *Natural History*, the name of a stone found in some parts of Persia, seeming to be the same as the mithridax or mithrax.

MITHRIDAX, the name of a gem described by Solinus, to which he ascribes qualities the same with those given by Pliny to the mithrax; and therefore probably the same stone with it.

MITIUSCHOV, in *Geography*, an island in the Frozen ocean, near the western coast of Nova Zembla, at the entrance of the Metochik Schau. N. lat. 75° 20'. E. long. 55° 38'.

MITOC, a lake of Thibet, about 36 miles in circumference. N. lat. 31° 50'. E. long. 93° 24'.

MITOMBA, a kingdom of Africa, in the country of Sierra Leona, situated on the banks of the river Sierra Leona, called also Mitomba.

MITRA, in *Botany*. See HELVELLA, MITREOLA, and OPHIORRHIZA.

MITRALIS VALVULA, in *Anatomy*, the valve placed at the opening, by which the left auricle and ventricle communicate. See HEART.

MITRARIA, in *Botany*, so denominated from a slight resemblance to a mitre, in the form of the outer calyx.— Cavan. Ic. v. 6. 57.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personatæ*, Linn. *Scrophulariæ*, Juss.

Gen. Ch. *Cal.* Perianth double, inferior, permanent, each of one leaf: the outer divided on one side nearly to the bottom, on the other but half way down; the segments ovate, concave, of equal lengths: inner about the same length, in five, deep, lanceolate, nearly equal segments. *Cor.* of one petal, ringent; tubes many times longer than the calyx, round, inflated upward, contracted at the mouth, pervious; limb short, spreading, in two lips; the upper in two parallel lobes; lower in three very deep ones; all ovate and obtuse. *Stam.* Filaments four, awl-shaped, two rather the longest, all longer than the corolla, inserted into the

bottom

bottom of its tube, with the rudiment of a fifth; anthers ovate, two-lobed. *Piſt.* Germen ſuperior, ovate; ſtyle awl-ſhaped, rather longer than the ſtamens; ſtigma ſlightly ſwelling, obtuſe. *Peric.* Berry ſucculent, of one cell. *Seeds* numerous, oblong, poliſhed, imbedded in pulp.

Obſ. It is to be preſumed that the germen has two cells, though they are obliterated in the ripe fruit. The double calyx diſtinguiſhes this genus from *Beſleria.*

Eſſ. Ch. Calyx double; the outer in two lobes; the inner in five. Corolla two-lipped; the lower lip in three equal entire ſegments: tube inflated. Berry ſuperior, of one cell, with many ſeeds.

1. M. *coccinea.* Cavan. Ic. t. 579.—The only known ſpecies. Gathered by Lewis Née at St. Carlos, in Chili, flowering in February. *Stem* ſhrubby, climbing; with weak oppoſite, ſquariſh, ſlightly downy, jointed, leafy *branches.* *Leaves* oppoſite, ſometimes three together, (as often happens to the ſhrubs of that country, witneſs *Fuchſia, Verbena,* and others,) on ſhort ſtalks, ovate, acute, ſtrongly ſerrated, about an inch long; green and ſlightly hairy above; glaucous beneath. *Flowers* on ſimple axillary ſtalks about the length of the leaves, uſually ſolitary, ſometimes two or three together, drooping, ſwelling and roughiſh towards the top. *Calyx* green; the outer one hairy. *Corolla* an inch and half long, of a rich ſcarlet. *Stamens* and *ſtyle* ſcarlet, with yellow anthers. *Berry* globoſe, the ſize of a currant, tipped with the permanent ſtyle.

MITRASACME, from μίτρα, *a biſhop's mitre,* and ακμη, *the ſummit;* Labillardiere ſays "ακμη, *the flower,*" probably by an accidental miſtake, or miſconception. He invented this name for the plants in queſtion, becauſe the acute ſummit of the germen ſeparates, as it advances to maturity, into two points, each crowned with half the divided ſtyle, and reſembles the cloven termination of a mitre. Mr. Brown, though he adopts the name without alteration, obſerves, that *Mitragyne* would have been better. Labillard. Nov. Holl. v. 1. 36. Brown Prodr. Nov. Holl. v. 1. 452.—Claſs and order, *Tetrandria Monogynia.* Nat. Ord. *Rotaceæ,* Linn. *Gentianæ,* Juſſ. Brown. Labillardiere refers it to the *Scrophulariæ* of Juſſieu, but certainly erroneouſly.

Gen. Ch. *Cal.* Perianth inferior, angular, in four, rarely but two, deep, acute, ſlightly ſpreading, permanent ſegments. *Cor.* of one petal, deciduous; tube angular, ſhort; limb ſlightly ſpreading, in four deep, equal ſegments. *Stam.* Filaments four, awl-ſhaped, inſerted into the tube, equal, uſually ſhorter than the corolla; anthers heart-ſhaped, incumbent. *Piſt.* Germen ſuperior, ovate, acute, ſhorter than the calyx, cloven at the point; ſtyle terminal, thread-ſhaped, the length of the corolla, ſoon ſplitting lengthwiſe at the baſe, and finally all the way up; ſtigma capitate, two-lobed, finally divided. *Peric.* Capſule ovate, pointed, of two valves and two cells, the partitions from the inflexed margins of the valves, its apex ſplitting into two parts, each crowned with half the ſtyle, but ſtill cloſed by the reſpective partitions. *Seeds* numerous, ſmall, roundiſh, affixed to the central receptacles.

Eſſ. Ch. Calyx angular, four-cleft. Corolla deciduous, four-cleft, regular; its tube angular. Capſule ſuperior, with two cells and many ſeeds, divided at the top. Style divided at the baſe. Stigma capitate.

This genus is moſt akin to Exacum, (ſee that article,) but ſufficiently diſtinct. Labillardiere deſcribes but one ſpecies, Brown nineteen, of which the firſt ſixteen anſwer moſt perfectly to the generic characters. We ſhall deſcribe Mr. Brown's firſt and fourth ſpecies, as well as M. Labillardiere's.

M. *polymorpha.* Br. n. 1.—Umbel partly compound. Flower-ſtalk elongated, ſmooth like the calyx, whoſe ſegments are naked at the ſummit. Leaves linear, ſomewhat fringed. Stem erect, hairy.—Gathered by Dr. White, as well as Mr. Brown, near Port Jackſon, New South Wales. The *root* ſeems to be annual. *Stems* ſeveral, erect, from three to ſix inches high, ſimple, or ſlightly branched, leafy, round, hairy. *Leaves* oppoſite, in pairs croſſing each other, ſeſſile, three quarters of an inch long, pale, linear, keeled, revolute, entire, obtuſe with a ſmall point; more or leſs fringed towards the baſe; ſmooth above; ſometimes hairy beneath. *Flower-ſtalks* terminal, longer than the ſtem, round, very ſmooth, ſimple or divided, terminating in an *umbel* of two, three, or four flowers, on long ſlender ſmooth ſtalks, one of which ſtalks often bears a lateral flower alſo, ſo that the umbel is then rather a *cyme.* A pair of ſhort leaves accompanies the baſe of the *umbel.* The *calyx* is entirely ſmooth, pale, with green angles. *Corolla* white or purpliſh, bearded within, twice as long as the calyx. The *flowers* and *infloreſcence* are not unlike *Androſace lactea,* Curt. Mag. t. 868, 981, in their general aſpect.

M. *caneſcens.* Br. n. 4.—Umbel about three-flowered, ſeſſile; its ſtalks ſmooth. Segments of the calyx bearded at the tips. Leaves linear, obtuſe, hairy on both ſides. Stem procumbent, hairy all over; with aſcending branches.—Native likewiſe of Port Jackſon. *Root* perennial. *Herb* much like the laſt but very hairy, and of a darker hue. The *umbels,* which have at moſt but three flowers, are accompanied at the baſe by a pair of ſhort ovate hairy *leaves,* and ſtand each at the top of an elongated hairy branch. *Calyx* ſmooth, except a little briſtly tuft at the point of each ſegment. *Corolla* pale blue or purpliſh, with ſomewhat broader rounder ſegments than the foregoing.

M. *piloſa.* Labill. Nov. Holl. v. 1. 36. t. 49. Br. n. 15.—Creeping, hairy. Leaves ſtalked, ovate, fringed. Flower-ſtalks axillary, ſolitary, about the length of the leaves. Calyx hiſpid.—Native of moiſt places in Van Diemen's land. *Labillardiere.* *Root* perennial, branched. *Herb* hairy, procumbent, branched. *Stem* round, hollow. *Leaves* oppoſite, rather fleſhy, ovate, entire, about half an inch long, tapering at the baſe into a ſhort *footſtalk.* *Flower-ſtalks* ſometimes ſhorter, ſometimes longer than the leaves, round, ſimple, ſingle-flowered. *Calyx* hairy all over. *Corolla* finely downy within; its limb ſhort, in four ſhallow lobes.

All the ſpecies are herbaceous, ſome ſmooth, ſome hairy. *Leaves* ſometimes all crowded about the root; always ſimple, undivided and entire.

None of theſe plants have been raiſed in Europe.

MITRAVINDA, in *Hindoo Mythology,* one of the eight wives aſſigned to Kriſhna.

MITRE, Mitra, from Μιτρα, which ſignifies the ſame; a pontifical ornament, worn on the head by biſhops, and certain abbots, on ſolemn occaſions.

The mitre is a round cap pointed, and cleft at top, with pendants hanging down on the ſhoulders, and fringed at both ends. The biſhop's is only ſurrounded with a fillet of gold, ſet with precious ſtones; the archbiſhop's iſſues out of a ducal coronet. Theſe are never uſed otherwiſe than on their coats of arms. Abbots wear the mitre turned in profile, and bear the croſier inwards, to ſhew that they have no ſpiritual juriſdiction without their own cloiſters.

The pope has alſo granted to ſome canons of cathedrals the privilege of wearing the mitre. The counts of Lyons are alſo ſaid to have aſſiſted at church in mitres.

In Germany, ſeveral great families bear the mitre for their creſt; to ſhew that they are advocates, or feudatories, of ancient abbeys, or officers of biſhops, &c.

The

The pope has four mitres, which are more or less rich, according to the solemnity of the feast-days they are to be worn on. The mitre was originally the women's head-dress, as the hat was that of the men. This appears from Remulus in Virgil, who reproaches the Trojans, that they were dressed like women, and wore mitres,

"Et tunicæ manicas & habent redimicula mitræ."

The cardinals anciently wore mitres, before the hat, which was first granted them by the council of Lyons, in 1243. Authors make no mention of the mitre as an episcopal ornament, before the year 1000.

Mitre, in *Architecture*, is the workmen's term for an angle that is just 45 degrees, or half a right one.

If the angle be a quarter of a right angle, they call it a half-mitre.

To describe such angles, they have an instrument called the mitre-square; with this they strike mitre-lines on their quarters, or battens; and for dispatch, they have a mitre-box, as they call it, which is made of two pieces of wood, each about an inch thick, one nailed upright on the edge of the other; the upper piece hath the mitre-lines struck upon it, on both sides, and a kerf, to direct the saw in cutting the mitre-joints readily, by only applying the piece into this box.

Mitre is used by the writers of the Irish history for a sort of base money, which was very common there about the year 1270, and for thirty years before, and as many after. There were, besides the mitre, several other pieces called according to the figures impressed upon them, rosaries, lionades, eagles, and by the like names. They were imported from France, and other countries, and were so much below the proper currency of the kingdom, that they were not worth so much as a halfpenny each. They were at length decryed in the year 1300, and good coins struck in their place. These were the first Irish coins in which the sceptre was left out. They were struck in the reign of Edward, the son of our Henry III., and are still found among the other antiquities of that country. They have the king's head in a triangle full-faced. The penny, when well preserved, weighs twenty-two grains; the halfpenny ten grains and a half.

Mitre-*Sils*, in *Canals*, are the angular sils of lock-gates.

MITRED Abbots. See Abbot.

MITREKE, in *Geography*, a town of Arabia, in the province of Oman; 44 miles W. of Hassek.

MITREOLA, in *Botany*, a name given by Linnæus, in the first edition of his *Genera Plantarum*, to the *Mitra* of Houstoun, engraved in the nineteenth unpublished plate of that botanist, both names alluding to the resemblance of the minute capsule to a mitre. See Ophiorrhiza.

MITROVATZ, in *Geography*, a town of Sclavonia; 32 miles E.N.E. of Gradisca.

MITTA, in our *Old Writers*, is an ancient Saxon measure. Its quantity is not certainly known; but it is said to be *mensura decem modiorum*, a measure of ten bushels. Doomsday.

Mitta, or *mitcha*, being besides a measure for salt and corn, is used for the place where the cauldrons were put to boil salt. "Chalderias quoque ad sal conficiendum cum propriis sedibus mitchæ vocantur."

MITTAMPOUR, in *Geography*, a town of Hindoostan, in Rohilcund; 20 miles S.W. of Bissowla.

MITTAW, the capital of the duchy of Courland, the residence of the duke and of the regency of the country, situated on the river Aa, in that part of the duchy called "Semigallia." The town is extensive, containing within its circuit many gardens and vacant spaces. The walls and moats are decayed, and the houses are destitute of elegance; nevertheless it is tolerably well inhabited. It has two Lutheran churches, a beautiful Calvinistic church, and a Popish church. The town school, though the principal in the country, is not flourishing. The palace, built by the late duke, is a pile of buildings, in which are spacious and handsome apartments almost wholly unfurnished. The academy, constituted at a great expence, contained, in May 1785, almost as many professors as students, the former being eight, and the latter twenty; 56 miles W. of Riga. N. lat. 56° 38'. E. long. 23° 10'.

MITTELWALD, or Miedzibor, a town of Silesia, in the principality of Oels; 16 miles N.E. of Oels. N. lat. 51° 23'. E. long. 17° 40.—Also, a town of Silesia, in the county of Glatz, on the Neisse, near its source, and on the borders of Bohemia; 27 miles S. of Glatz. N. lat. 50° 2'. E. long. 16° 29'.

MITTENDARII, among the Romans, commissioners sent into the provinces by order of the *præfectus prætorii*, or captain of the guards, upon some public account, as to inspect the behaviour and management of provincial governors, and observe whatever was amiss; all which they were to lay before the prefect, who had authority to remedy such abuses.

MITTENDIS *Recordo & Processu*. See Recordo.

MITTENDO *Manuscriptum Pedis Finis*, in *Law*, a writ judicial, directed to the treasurer and chamberlains of the exchequer, to search for and transmit the foot of a fine, acknowledged before justices in eyre, into the common pleas, &c.

MITTENWALD, in *Geography*, a town of Bavaria, in the bishopric of Freysing; 10 miles N.N.W. of Innspruck.

MITTENWALDE, a town of Brandenburg, in the Middle Mark; 22 miles S.E. of Potzdam. N. lat. 52° 15'. E. long. 13° 32'.

MITTER l'Estate, and *Mitter le droit*. See Release.

MITTERBURG, in *Geography*, a town of Istria, and capital of a county, containing several churches and a convent; defended by a castle, which is situated on a rock; 30 miles S.E. of Trieste. N. lat. 45° 23'. E. long. 14° 7'.

MITTERSILL, a town of Salzburg, on the Salzbach; 36 miles S.S.W. of Salzburg.

MITTIMUS, in *Law*, a writ by which records are ordered to be transferred from one court to another; sometimes immediately, as out of the king's bench into the exchequer; and sometimes by a certiorari into the chancery; and from thence, by a mittimus, into another court.

Mittimus is also used for a precept in writing, directed by a justice of peace to a gaoler, for the receiving and safe-keeping a felon, or other offender, by him committed to the gaol.

This is a warrant under the hand and seal of the justice, containing the cause of the commitment of the offender.

MITTWEYDA, in *Geography*, a town of Saxony, in the circle of Leipsic; 30 miles W. of Dresden. N. lat. 50° 58'. E. long. 12° 52'.

MITU, or Mitu-porangu, in *Ornithology*, the name of a Brasilian bird of the pheasant kind, according to Margrave, and the generality of those who speak of it; but supposed by Mr. Ray rather to approach to the nature of the peacock or turkey-cock: and in the Linnæan system a species of the *crax*; the Crax *Alector*, which see.

MITYLENE, or Metelin, the ancient *Lesbos*, one of the

the moft confiderable iflands of the Grecian Archipelago, is fituated in the vicinity of the coaft of Natolia, which it feems to command, and it is placed at an equal diftance from the gulf of Smyrna and the channel of Conftantinople, not far from the principal iflands of the Archipelago. By this pofition the poffeffion of it is extremely important, more efpecially as its interior refources render it fufceptible of the moft flourifhing ftate. But being in the hands of the Turks, the advantages of its fituation are loft, and its population, agriculture, and induftry are from day to day diminifhing and falling into decay. In fome parts of the ifland, faid to be 36 miles long and 14 broad, are volcanic mountains and others compofed of marble, that extend almoft through the ifland: its mountains are covered with wood, particularly with pines that yield excellent pitch for the ufe of the dock-yard eftablifhed near the fouth harbour, and for the careening of the veffels and boats whch come to Mitylene for that purpofe. On thefe mountains are alfo found oaks, the arbutus, the andrachne, the lentifk, the turpentine tree, the myrtle, the agnus caftus, a few leguminous fhrubs, and feveral rock-rofes, among which is that which yields the ladanum. The "velana" oak is more common on the rifing grounds and in the plains than on the mountains. The elm grows in the low and watered places, and the plane tree is chiefly found on the brinks of the rivulets and torrents. The mountains alfo afford a variety of fprings, of which fome are medicinal. The vallies of the ifland are extremely fertile, well watered, and in fome degree cultivated, though in this refpect they admit of much improvement. The principal towns of this ifland are Mitylene and Molivo, which fee; and its harbours are port Caloni and port Olivier. At the head of port Caloni is a plain two leagues in extent, the principal culture of which confifts in corn, cotton, and olive trees; figs, mufk and water melons, pumpkins, and various legumes are alfo gathered here. Here are feveral villages; but the population is not proportioned to the fertility and extent of the foil adapted to culture. The air in this quarter is infalubrious, and often fatal; fo that thefe villages are inhabited only by poor Greek cultivators: the Turks, who are proprietors of lands, preferring a refidence at Mitylene, Molivo, and the other places that are beft fituated in the ifland.

Port Caloni lies in the middle of the fouthern part of the ifland; it is very extenfive and very fafe, but little frequented; none but veffels thwarted by the wind, or buffeted by a ftorm, anchoring here, and not one entering it to take in a cargo, or to unload. The other port, called port Yero or port Olivier, derives its name from the great number of olive trees which are planted in the adjoining plain, and on the declivity of the mountains and hills that furround it. In the eaftern part of the harbour, there are a few calcareous hills, which have not been attacked by the fire of volcanoes. Here is found near the fea a copious fpring of hot mineral water, much valued by the inhabitants of Mitylene. The captain-pacha has built here a bafin capable of containing 10 or 12 perfons; he has alfo repaired the building, which is occupied by the Turk charged to receive all thofe who wifh to make ufe of thefe waters; which are nearly two leagues from Mitylene. Port Olivier is one of the fafeft and moft fpacious harbours of the Archipelago; it lies at the eaftern and fouthern extremity of the ifland, and is faid to abound with fifhes and conchylia, among which are excellent oyfters, which are carried to Scio and Smyrna. It is frequented, during the whole year, by boats and veffels that come hither to load with the oil which is made in the environs. Although this ifland is expofed in winter to fudden gales of wind from the N.E. and the E., which come from the mountains of Afia, as well as to the N. wind, which reigns over the whole Archipelago, the climate is neverthelefs tolerably fine, and the temperature of the air fomewhat mild. It feldom freezes in that feafon; but in fummer the heat is rather powerful on the S. coaft, and the air is, in general, more unwholefome there than in the other parts of the ifland. This ifland is divided into lordfhips; but as the aga of other countries is obliged to join the land-forces when required at Mitylene, he is fubject to a maritime duty, from which he contrives to exempt himfelf by fome pecuniary facrifices. In Mitylene are reckoned 8000 Greeks paying the karatch, (capitation tax,) from the age of feven to their death; fo that the population may be eftimated at near 20,000, including the women and children above that age. It is thought that there are nearly as many Turks as Greeks in the ifland. which contains in all 40,000 inhabitants. The Jews are not fufficiently numerous to be taken into the calculation. According to an ancient cuftom in this ifland, the eldeft daughter alone inherits the property of the father and mother to the exclufion of the fons and other daughters. This cuftom has been long refpected and religioufly followed; but of late the patriarch of Conftantinople, the archbifhop, and all the clergy of Mitylene have fomewhat modified this law, by admitting all the daughters to a partition in a certain proportion. The quantity of oil which is exported from this ifland in ordinary feafons is eftimated at upwards of 50,000 quintals; almoft the whole of which is fent to Conftantinople. The oil is, in general, but of an indifferent quality, becaufe the inhabitants, not having a fufficient number of mills, are obliged to gather their olives flowly. Italy draws from Mitylene 8000 quintals of "Velanida," a part of which comes from the coaft of Afia. Dried figs are an article of exportation of little importance, as well as wool. Cotton, fefamum, filk, ivory, wax, and different fpecies of grain are gathered in a fmall quantity; but the laft are not fufficient for the fupply of the inhabitants, who draw a great quantity of wheat and barley from the coaft of Afia. They alfo import oxen, horfes, and mules for agriculture and draught, as well as part of the fheep that are killed at the flaughter-houfe. Wine is now fcarce, becaufe a great part of the grapes is employed by the Turks in making confection, and becaufe the Turks are accuftomed to convert the other into brandy. The wine of ancient Lefbos has loft its reputation, being fweet and ill-flavoured, as are, in general, all the wines of the Archipelago. Although there are no rivers in this ifland, a few torrents, fupplied by rain waters and fprings, ferve to furnifh fufficient water for confumption and for watering part of the plains, fo as to procure for the inhabitants legumes, herbage, and fruits.

In the channel formed by the ifland of Mitylene and the coaft, at the entrance of the Adramyttian gulf, are fome fmall iflands, which the Greeks call "Mufconifi," and navigators "Myconiffes," but formerly they bore the name of "Hecatones." They are faid to be fertile in wines and oil. For the ancient ftate of this ifland, fee Lesbos.

Mitylene, fometimes called "Caftro," or "Metelin," is the chief town of the ifland above defcribed. It contains 2 or 3000 Greeks, 3 or 4000 Turks, and 30 or 40 Jewifh families. The citadel is fpacious, provided with cannon in tolerably good condition, and defended by 5 or 600 janizaries, almoft all married and fettled. Within it are two mofques and a great number of houfes occupied by this militia. The modern town extends in a femicircle along the north harbours, on a part of the ground occupied by the ancient city; of the former grandeur of which fome remains are ftill vifible. Cicero de Leg. Agr. and Vitruvius, lib. i. c. 6. expatiate on its magnificence. Such was the flourifhing

flourifhing ftate of the fine arts in the city of Mitylene, called by Strabo η μεγαλη πολις, when Marcellus, after the battle of Pharfalia, returned to end his days there in literary eafe, that a modern traveller, after the lapfe of 17 centuries, could behold nothing but proofs of the fplendour to which they had attained. Tournef. Voy. du Lev. tom. ii. p. 81. See Lesbos.

The two harbours of Mitylene are feparated by a tongue of land, on which was conftructed by the Genoefe a citadel, which the Turks have preferved. The upper or north harbour is fecured from the N.E. wind by a jetty, the origin of which is carried back to ancient Greece. The fouth harbour is open and faces the S.E.; it is a little lefs extenfive and lefs deep than the other; none but the boats of the country can anchor in it, while the north harbour can admit fmall merchant veffels. Men of war and European fhips, which commerce attracts to Mitylene, anchor in fummer off the fouth harbour; but they fcarcely expofe themfelves there in winter, becaufe there happen fometimes in that feafon very impetuous gales from the N.E., which might occafion their deftruction, or oblige them to cut their cables, and get under fail with all expedition. There was formerly a canal of communication between thefe two harbours, which feparated the tongue of land juft mentioned, and formed of it an ifland, on which was built part of the town. Time has choked up the canal, but it has not deftroyed the jetty, which ran from the little ifland, and fheltered the north harbour from the worft weather. N. lat. 39° 20′. E. long. 26° 14′. Olivier's and Sonnini's Travels. Clarke's Travels, vol. ii.

MITZLER, Lorenz Christoph, of Kolof, in *Biography*, born in 1711, a fingular character and voluminous publifher on mufical fubjects. But before he meddled with mufic, his pretenfions were various. He fet off a doctor of phyfic, then got ordained a minifter of the Lutheran church, and next affumed the character of a counfellor learned in the law. After trying his hand at thefe profeffions, in mufic he appeared at firft a theorift and critic more than a practical mufician. In 1740, however, he compofed odes, which were mathematical, dry, and dull. Thefe were ridiculed throughout Germany. Matthefon is very jocular on his works; but Mitzler took all for ferious panegyric. Among his numerous productions fpecified by Gerber, (in his continuation of Walther's Mufical Lexicon,) many of which have, perhaps, never been read, there is no one which feems to have merited that honour. He died in 1778. If his life was of little ufe to the world, it muft be owned that he diligently tried to render the world ufeful to himfelf.

MITZUZ, in *Geography*, a town of Japan, in the ifland of Niphon; 110 miles W.N.W. of Jedo.

MIXCO, a town of Mexico, in the province of Guatimala; 25 miles E. of Guatimala.

MIXEN, in *Agriculture*, a term applied to a compoft dunghill. See Compost and Manure.

MIXING *of Mortar*. See Mortar.

MIXIS, Μιξις, *Mixture*, in the *Ancient Mufic*, was one of the parts of Greek melopœia, by which the compofer was inftructed how to combine intervals properly, and diftribute them in different genera and modes, according to the character of the melody propofed. See Melopœia.

MIXO-LYDIAN, the name of one of the modes of ancient mufic, called alfo *Hyper-Dorian;* which fee. The mixo-lydian mode was the moft acute of the feven modes to which Ptolemy had reduced all the modes of the Greek mufic. (See Mode.) This mode was faid to be affecting and paffionate, exciting great emotions, and therefore applicable to tragedy. Ariftoxenus affures us, that it was invented by Sappho; but Plutarch avers, that ancient fables afcribe it to Pythoclides. He alfo fays that the Argians fined muficians who firft adopted it, and who had introduced into mufic the ufe of feven ftrings; that is, making the feventh ftring a key-note.

MIXT, or Mixed *Body*, in *Philofophy*, is that which is compounded of divers elements or principles.

By which *mixt* ftands contradiftinguifhed from *fimple*, or *elementary*, which is applied to bodies confifting of one principle only.

The fchoolmen define a mixt body to be a whole refulting from feveral ingredients, altered, or new modified, by the mixture. On which principle the feveral ingredients do not actually exift in the mixt; but they are all changed, fo as to confpire to a new body, of a different form from that of any of the ingredients. But the modern philofophers rarely conceive the term in fo much ftrictnefs. The bufinefs of chemiftry, we fay, is to refolve mixt bodies into their principles, or component parts.

The fchool philofophers diftinguifh mixt bodies into perfect and imperfect.

Mixts, *Perfect*, are the clafs of organized and animated bodies, where the elements, or ingredients of which they are compofed, are changed, or transformed, by a perfect mixture. Such are plants, beafts, and men.

Mixts, *Imperfect*, are unorganized and inanimate bodies, the forms of which remain ftill the fame as of the ingredients that conftitute them. Such are meteors, minerals, metals, &c.

Mixt, in *Chemiftry*. See Aggregate.

Mixt, or *Mixed Action*, in *Law*. See Action.

Mixt *Angle, Fable*. See Angle, and Fable.

Mixt *Figure*, in *Geometry*, is that which confifts partly of right lines, and partly of curve lines.

Mixt *Force, Hiftory, Mathematics*. See Force, History, and Mathematics.

Mixt, or *Mixed Larceny*. See Larceny.

Mixt *Mode*. See Mode.

Mixt *Number*, in *Arithmetic*, that which is partly an integer, and partly a fraction: as $4\frac{1}{2}$.

Mixt *Obligation*. See Obligation.

Mixt *Ratio*, or *Proportion*, is when the fum of the antecedent and confequent is compared with the difference between the antecedent and confequent: as if $\begin{matrix} 3 : 4 :: 12 : 16 \\ a : b :: c : d \end{matrix}$

then $\begin{matrix} 7 : 1 :: 28 : 4 \\ a + b : a - b :: c + d : c - d. \end{matrix}$

Mixt *Salts, Stairs, Service*. See Salts, Stairs, and Service.

Mixt *Tithes*, are thofe of cheefe, milk, &c. and of the young of beafts. See Tithe.

MIXTILINEAR Angle. See Angle.

MIXTION, Mixtio, or *Miftio*, the act of mixing; or the union and coalition of divers corfpucles into one body. The Peripatetics, who hold an alteration effential to mixtion, define it the union of feveral altered ingredients, or mifcibles.

Mixtion makes a confiderable operation in the chemical and Galenical pharmacy; where divers powders, fpecies, and other fimples, are faid to be *mixed, mifceri*, though without any communication, or tranfition of the virtues of one into thofe of another. See Combination and Composition.

MIXTURE, Mescolanza, a connection in the modes of canto-fermo, in chants which go higher or lower than the octave, and modulate into another mode, participating both

both of authentic and plagal. The mixture is only practicable in modes that go in pairs, as the firſt mode or tone, and the ſecond, the third with the fourth, the plagal with the authentic, and reciprocally.

MIXTURE, the name of a ſtop in the full organ, repeating the ſame intervals of the octave in the key of C throughout the ſcale. See FURNITURE.

MIXTURE, *Mixtura*, or *Miſtura*, in a philoſophical ſenſe, is an aſſemblage, or union, of ſeveral bodies of different properties, in the ſame maſs.

To determine the ratio of the ingredients of a mixture, is that celebrated problem propoſed by Hiero, king of Syracuſe, to Archimedes, on occaſion of a crown of gold, in which the workman had fraudulently mixed ſilver; the ſolution of which was matter of ſo much tranſport to that divine mechanic. See HIERO's *Crown*.

MIXTURE, in *Matters of Drapery*, denotes the union or blending of ſeveral wools of different colours, not yet ſpun. Hence a mixture, or mixed ſtuff, is that whoſe wool and warp are of wools of different colours, dyed and mixed before they were ſpun. See CLOTH.

MIXTURE, in *Pharmacy*, differs from a julep in this reſpect, that it receives into its compoſition not only ſalts, extracts, and other ſubſtances diſſoluble in water, but alſo earths, powders, and ſuch ſubſtances as cannot be diſſolved.

Mixtures depend upon diffuſion and ſuſpenſion in any liquid of inſoluble ſubſtances minutely divided; and for this purpoſe, it is often neceſſary that the liquid itſelf ſhould be rendered more denſe by the addition of ſome viſcid matter, as mucilage or ſyrup. Mixtures are ſometimes denominated from their medical properties and effects; ſuch as aſtringent, diuretic, laxative, &c. but moſt commonly from the name of the principal ingredient uſed in their compoſition. The London college includes under the general head of mixtures thoſe medicines which have uſually been denominated *emulſions*. See EMULSION.

The principal mixtures are the following:

Miſtura ammoniaci, Mixture of gum ammoniac, P. L. is formed by rubbing two drachms of gum ammoniac with half a pint of water gradually poured upon it, until they are perfectly mixed. A ſimilar preparation, under the name of *lac ammoniæ*, milk of ammoniac, is ordered by the Dublin college to be made by triturating a drachm of gum ammoniac in eight fluid-ounces of penny-royal water, gradually adding the water until the mixture acquires the appearance of milk, and then ſtraining it through linen. This preparation is beneficially employed as an expectorant in doſes of from f. ℥ſs to f. ℥j, combined with an equal quantity of almond mixture.

Miſtura amygdalæ, Almond mixture, P. L. 1809, Lac amygdalæ, P. L. 1787, Emulſio communis, P. L. 1745, is prepared by gradually adding a pint of diſtilled water to two ounces of almond confection, and rubbing them together. A ſimilar mixture, called *emulſio amygdalæ communis*, almond emulſion, in the Edin. diſp. is prepared by well beating an ounce of blanched ſweet almonds in a ſtone mortar, gradually adding 2½ lbs. of water, and then ſtraining. The *lac amygdalæ*, almond milk of the Dub. coll. is formed by rubbing 1½ oz. of ſweet almonds blanched with ½ oz. of purified ſugar, adding gradually 2½ pints of water, and then ſtraining. The *emulſio mimoſæ niloticæ*, emulſio arabica, Edin. or emulſion of gum arabic, is made in the ſame manner as the almond emulſion, 2 oz. of gum arabic being added during the trituration of the almonds. The *Arabic emulſion*, Dub. is prepared by diſſolving two drachms of gum arabic in powder in a pint of warm decoction of barley, and when it is almoſt cold, pouring it gradually upon half an ounce of blanched ſweet almonds beaten to a paſte, with the ſame quantity of purified ſugar, triturating at the ſame time ſo as to form a milky mixture; and then ſtraining.

The mixtures above deſcribed are uſed as diluents and demulcents in inflammatory fevers, ſtrangury, dyſury, and other affections of the urinary organs; but they are principally employed as vehicles for the exhibition of more active remedies. The doſe is from f. ℥ij to oſs frequently repeated.

Miſtura aſſafœtidæ, Mixture of aſſafœtida, P. L. 1809, Lac aſſafœtidæ, P. L. 1787, is prepared by rubbing two drachms of aſſafœtida with half a pint of water, gradually poured upon it, until they are perfectly mixed. The *lac aſſafœtidæ*, milk of aſſafœtida, Dub. is obtained by triturating a drachm of aſſafœtida with eight fluid-ounces of penny-royal water gradually added until an emulſion is formed. This mixture is chiefly uſed as an enema in flatulent colic, worms, and convulſions of infants occaſioned by irritation of the bowels during dentition. When given by the mouth, the doſe may be from f. ℥ſs to f. ℥jſs often repeated.

Miſtura camphoræ, Camphor mixture, P. L. 1809, Miſtura camphorata, P. L. 1787, Julepum é camphora, P. L. 1745, is formed by rubbing half a drachm of camphor with 10 minims of rectified ſpirit, then adding gradually a pint of water, and ſtraining the liquor. The *miſtura camphorata*, Dub., camphorated mixture, is prepared by rubbing a ſcruple of camphor with 10 drops of rectified ſpirit of wine, and then with half an ounce of refined ſugar, adding a pint of water during the trituration, and ſtraining the mixture through linen. This is an elegant vehicle for more active remedies in low fevers and nervous affections. The doſe is from f. ℥j to f. ℥ij, given every three or four hours. The *emulſio camphorata*, Edin., camphorated emulſion, is made of a ſcruple of camphor, two drachms of ſweet almonds blanched, a drachm of refined ſugar, and 6 oz. of water, in the ſame manner as the common almond emulſion. This is given with advantage in typhus and nervous caſes in doſes of f. ℥ij, every three or four hours. See CAMPHOR.

Miſtura cornu uſti, Mixture of burnt hartſhorn, P. L. 1809, Decoctum cornu cervi, P. L. 1787, Decoctum album, P. L. 1745, is prepared in the manner deſcribed under *Hart's* HORN.

Miſtura cretæ, Chalk mixture, P. L. 1809, Miſtura cretacea, P. L. 1787, Julepum é creta, P. L. 1745, is formed by mixing half an ounce of prepared chalk, three drachms of refined ſugar, half an ounce (an ounce Dub.) of acacia gum powdered in a pint of water. The *potio carbonatis calcis*, olim, *potio cretacea*, Edin., chalk potion, is made by rubbing together 1 oz. of prepared carbonate of lime (chalk), ½ oz. of refined ſugar, 2 oz. of mucilage of gum arabic, then gradually adding 2½ lbs. of water and 2 oz. of ſpirit of cinnamon, and mixing them.

Theſe preparations of chalk are given in acidity of the primæ viæ, and combined with opium or catechu in diarrhœa. The doſe is from f. ℥j to f. ℥ij, given every three or four hours; or after every liquid evacuation.

Miſtura ferri compoſita, Compound mixture of iron, P. L. 1809, is prepared by rubbing together a drachm of powdered myrrh, 25 grains of ſubcarbonate of potaſs, and a drachm of refined ſugar, and during the trituration adding gradually, firſt, 7½ oz. of roſe-water and half a fluid-ounce of ſpirit of nutmeg, and laſtly, a ſcruple of ſulphate of iron powdered. The mixture ſhould be immediately poured into a proper glaſs bottle and ſtopped cloſe. The myrrh requires to be well dried before it can be reduced to powder. This mixture, which is very ſimilar to the celebrated antihectic

hectic mixture of Dr. Griffiths, is a compound very commonly directed as an useful tonic, particularly in hysteria and chlorosis, and in phthisis, when no active inflammatory diathesis subsists. The dose is from f. ℥j to f. ℥ij, given two or three times a day.

Mistura guaiaci, Mixture of guaiacum, P. L. 1809, Lac guaiaci, P. L. 1787, is made by rubbing 1½ drachm of guaiacum gum-resin with two drachms of refined sugar; then with two fluid-drachms of mucilage of acacia gum, and when they are mixed, pouring on gradually eight fluid-ounces of cinnamon water. This is administered in doses of from f. ℥ss to f. ℥ij, two or three times a day; diluting freely with tepid barley water or gruel for aiding its operation.

Mistura moschi, Musk mixture, P. L. 1809, Mistura moschata, P. L. 1787, Julepum è moscha, P. L. 1745, is prepared by rubbing a drachm of musk with the same quantity of refined sugar, then with the same quantity of acacia gum powdered, and adding by degrees six fluid-ounces of rose-water. This may be given to the quantity of f. ℥ij every three or four hours in spasmodic affections and the sinking state of typhus. The late Mr. White of Manchester found this mixture combined with ammonia ℈ss, spirit of lavender f. ʒi, and spirit of juniper f. ʒj, very useful in sloughing phagedenic ulcers of a syphilitic and strumous nature.

MIZAEL, in *Geography*, a town of Norway, in the diocese of Drontheim; 44 miles N.E. of Romsdal.

MIZELL, a town of Bohemia, in the circle of Boleslaw; nine miles S.E. of Jung Buntzel.

MIZEN. See Misen.

MIZEN-HEAD, in *Geography*, supposed to be the Notium of Ptolemy, a cape of the county of Cork, Ireland, being the south-western extremity of the island as well as of the county of Cork. N. lat. 51° 23′. W. long. 9° 43′.

Mizen-head, a cape of Ireland, in the county of Wicklow, on the E. coast between Wicklow-head and Arklow. N. lat. 52° 52′. W. long. 6° 4′.

MIZNEPHETH, in the *Jewish Antiquities*, a kind of mitre worn by the high-priest. See Cidaris.

MIZQUITL, in *Botany*, a name used by some authors for that species of the acacia, or Egyptian thorn, whose unripe fruit affords the inspissated juice, which is the true succus acaciæ of the shops, and whose gum naturally flowing from the trunk and branches is the true gum arabic.

MIZZY, in *Agriculture*, a term sometimes applied to a bog, or a quagmire.

MLIOWNOWY, in *Geography*, a town of Poland, in the palatinate of Kiev; 40 miles S.W. of Czyrkasy.

MLLAVA, a town of the duchy of Warsaw; 40 miles N.N.E. of Plozk.

MLODE, a town of Poland, in the palatinate of Kiev; eight miles S.E. of Bialacerkiew.

MNAKEH, a town of Arabia, in the province of Yemen; 12 miles W. of Sana.

MNASIUM, in *Botany*, is most probably named by Schreber from some resemblance to the μνάσιον of Theophrastus, an Egyptian plant, eatable like *papyrus*, and of a very sweet taste. Mart. Schreb. 214. Willd. Sp. Pl. v. 2. 22. Mart. Mill. Dict. v. 3. (Rapatea; Aubl. Guian. v. 1. 305. Juss. 44. Lamarck Illustr. t. 226.)—Class and order, *Hexandria Monogynia*. Nat. Ord. *Ensatæ*, Linn. *Junci*, Juss.

Gen. Ch. *Cal.* Spatha of two, ovate valves, terminated by a linear, spreading leaf. Perianth inferior, of one leaf, divided into three, lanceolate, concave, acute, bordered segments. *Cor.* of one petal; tube very short; limb cloven into three, deep, lanceolate, concave, acute segments. *Stam.* Filaments six, very short, inserted into the tube; anthers long, square, terminated by an ovate, excavated, acute leaflet. *Pist.* Germen superior, three-lobed, roundish, marked with three streaks; style very long, striated; stigmas three, spirally twisted together. *Peric.* and *Seeds* unknown.

Eff. Ch. Spatha of two valves, many-flowered. Calyx three-cleft. Corolla of one petal, three-cleft, with a very short tube. Anthers terminated by a leaflet. Stigmas three, spirally twisted.

1. M. *paludosum.* Willd. and Martyn. (Rapatea paludosa; Aubl. Guian. t. 118.)—Native of woods, marshes, and the banks of rivers in Guiana, flowering in June.—*Root* perennial, woody, fibrous. *Stalks* numerous, naked, two feet high, striated, compressed, bordered, gradually broader towards the top, and springing from the bosoms of the radical leaves. *Leaves* very long, narrow, acute, smooth, striated, entire; sheathing at the base, and mutually embracing each other; narrower above the sheath. *Flower-stalks* scaly beneath the base of the calyx. *Corolla* yellow.

Willdenow observes, that *Mnasium* has greatly the habit of a *Pontederia*, but that it differs materially from that genus in the structure of its flowers.

MNEME-CEPHALICUM Balsamum, the name of a famous compound balsam, said to have been purchased from a certain English physician by Charles duke of Burgundy, at the price of 10,000 florins. Some who have been very lavish in its praises have affirmed, that it has a power of preserving in the mind the remembrance of all things that are past; but this kind of praise seems to be extravagant and unfounded; insomuch, that we think it needless to enumerate the ingredients of which this famous balsam (which we regard as fabulous in the effects ascribed to it) consists. We shall therefore content ourselves with referring to Sennertus' account of it in his Pract. lib. i. cap. 5.

MNEMONIC Tables. Among the artifices to assist the memory, this is one of great use.

Mnemonic tables exhibit in a regular manner, what is to be remembered of the same subject. And although the sciences ought to be taught in a scientifical manner, as much as possible, and that every thing should be so placed as to be intelligible and demonstrable from what has preceded it; yet tables ought not to be rejected, as they are helps to retain the doctrines of which the mind has had sufficient evidence. In such tables the properties of things are to be expressed concisely; illustrations and demonstrations should be left out, as the proposition ought to have been made sufficiently clear and certain, before it is registered in the table. Hence, the contents of such tables ought only to be the definitions, and the propositions relative to the subject. If a subject require a long table, this may be subdivided into smaller; by making first a table of the most general heads, and referring from each of these heads to a separate table; by this means the order and connection of the whole will be preserved. Such tables would produce a local and artificial memory, of great use to the retention and recollection of things. They would greatly facilitate a distinct view of the properties of their subjects, and facilitate recapitulation. Besides, as the expressions used in such tables ought to be very concise, so as just to be sufficient to excite the idea of the object to be remembered, soon after that idea has been acquired; after some time a certain obscurity will be found in perusing the tables, which will give us timely warning that our ideas begin to fade, and that they ought to be renewed. And this may be done without much trouble, if not too long delayed.

MNEMONICA, formed of μνημονευω, I retain in memory, denotes the art of memory. Under the article MEMORY we have illustrated the nature and operation of this faculty, and mentioned some of the principal methods, both ancient and modern, which have been invented for aiding the exercise of it. Since that article was printed, we have had an opportunity of perusing a publication, entitled "The Art of Memory, founded upon the principles taught by M. Gregor Von Feinaigle," &c. The author has, with great industry of research, detailed the principal systems of artificial memory, both before and after that of Mr. Grey was announced to the public in his "Memoria Technica," of which we have given a concise account under the article above cited. It sufficiently appears, without any laboured proof, that the principal expedient for assisting the memory is derived from association; and of this expedient Simonides, Cicero, and Quintilian availed themselves in the contrivances which they suggested for this purpose. Having fixed upon certain symbols of the subjects which they wished to recollect, they would transfer these symbols to the different compartments of a house, or public building, or to the different parts of the walls of a city, a public road, or a picture, and when these compartments, &c. presented themselves to view, or occurred in recollection, they would suggest the symbols attached to them, and these symbols would revive the remembrance of the sentences or subjects, or parts of those sentences, to which they appertained: and thus, by means of such compartments and symbols, a whole discourse might be committed to memory, and recollected when occasion required. Upon these principles, as we have reason to believe, was founded the topical memory of the ancients; and from this source, without doubt, are derived all the various systems of local and symbolical memory, that have been practised in more modern times.

Bradwardine seems to have been the first, who in this country made an attempt to form a system of topical memory on the plan of the ancients. (See BRADWARDINE.) The "Ars Memorativa" of Publicius, probably printed before the year 1482, treats of the arrangement of places, and the combination of images, and has been the fountain whence many subsequent writers have derived considerable information. Grataroli, in his "Castel of Memorie," a translation of which by W. Fulwood was published at London in 1562, and Thomas Watson of Oxford, in his MS. entitled "Artificiosæ Memoriæ Libellus," dated 1583, preserved in the British Museum, have referred to the ancient plan of dividing houses and walls for the assistance of the memory. J. Baptista Porta, in his "Ars Reminiscendi," printed at Naples in 1602, treats, like the authors already mentioned, of places and images; exchanges figures for symbols; represents letters by symbols, and gives two alphabets, one consisting of letters formed from various objects, and another, in which they are deduced from the different positions of the human body. Schenckel, a native of Bois-le-Duc, in 1547, and the author of "Gazophylacium Artis Memoriæ," published in 1610, propagated his discoveries in the mnemonic art through the Netherlands, Germany, and France, and they were received with great applause. The performances of this author excited astonishment; he repeated 40 sentences of some length, without any connection, and after merely writing them down and reading them twice, backwards and forwards, and in any order that was desired. Some of his pupils also distinguished themselves in a still more surprising manner. A German translation of Schenckel's work was published by Dr. Klüber, in 1804, under the title of "Compendium der Mnemonik, &c." The treatise of John Willis, entitled "Mnemonica &c." Lond. 1618, and a translation of which by Sowersby was published at London in 1661, contains many curious particulars. His plan is that of a topical memory, or of a memory to be assisted by some suitable edifice, and its appropriate divisions. The "Ars Memoriæ localis," published at Leipsic in 1620, and written by one of the professors of the university, merits preference, according to Morhof in his "Polyhistor," to all the treatises on mnemonics for perspicuity and arrangement. Morhof, in his dissertation "De Arte Lulliana" (see Polyhistor, T. t. l. 2. c. 5.) has preserved an elaborate account of Raymund Lully's system of artificial memory, to which he directed his attention at a very early period, and he is supposed to have been the first among the moderns who practised this art. (See the article LULLY.) D'Assigny's "Art of Memory," a third edition of which was published in London in 1706, contains many useful observations on the importance of a retentive memory, and on the mode of aiding the exercise of it; but it closes with some fanciful receipts for "comforting the memory," principally taken from early writers on this subject, and hardly deserving to be rescued from oblivion. Buffier's "Pratique de la Memoire Artificielle, &c." 8vo. Paris, 3 tom. 1719—1723, is intended to facilitate the acquisition of chronology and universal history, and his system is said to be ingenious and simple. Of Grey's "Memoria Technica" we have given a concise account under the article *Artificial* MEMORY; more need not here be said, as this useful manual is in almost every one's possession. Lowe's "Mnemonics delineated in a small Compass and easy Method, &c." 8vo. Lond. 1737, is considered by Dr. Watts as a material improvement of Grey's treatise, and accordingly it has been annexed to the eighth and last edition of that work. In Feyjoo's "Cartas Eruditas y Curiosas," 4to. 5 tom. Madrid 1781, there is a dissertation on remedies for the memory, and one on the art of memory. In another essay, the principles of the art are stated to consist in particular places and images, and a sphere or globe is divided into various compartments. In a section of this essay, Feyjoo speaks of remembering certain words by the means of images, and in another section he illustrates the application of the art to poetry. Since the posthumous publication of these essays, the author having died in 1765, after having been with difficulty saved from the horrors of the Inquisition, for the freedom of his censures on the licentiousness of the clergy, and the superstitions of the Romish church, (see FEYJOO,) no mention of the local and symbolical memory occurs until the year 1806, when it was announced in the "Philosophical Magazine," (vol. xxvi. p. 282.) that the study of the science of mnemonica was revived in Germany. In 1807, M. Gregor Von Feinaigle, a native of Baden, visited Paris, and delivered lectures on his "New System of Mnemonics and Methodics."

In 1811, M. Feinaigle visited England; and in June of that year he obtained leave from the managers of the "Royal Institution" to exhibit to the public an experiment of the efficacy of his method "of facilitating and assisting memory."—"Four children, two boys and two girls, all under 14 years of age, had been put under M. Feinaigle's care but two or three days before: he had one of the girls but an hour and a half; and the longest tuition that any of them had received was but four hours and a half.—One of them repeated Goldsmith's Hermit backward and forward, and stated the stanza, the line, and the order of any remarkable word required of him.—One little girl answered to questions in the chronology of the Roman emperors; and another multiplied, without slate or paper, two sums of eight figures by eight, and declared that she had not previously been taught arithmetic.—A boy determined the geographical

cal situation, in degrees and minutes, of 50 different cities; and on a planisphere chalked out on a board, marked down the true situation of places named to him.—Mr. Fincher, of the Institution, also recited the mineralogical tables of Haüy, the second part of which he had taught himself on M. Feinaigle's system, together with the first part of Brisson's ornithologic system; and he declared, from his own experience, that the principles of M. Feinaigle's art were equally calculated to give facility in the acquisition, and certainty in the retention, of the tables of any other science—a fact which was confirmed by several gentlemen present, who have attended the private courses of the professor."—M. Feinaigle has since that time repeated his exhibitions at Liverpool, in Scotland, and in London, to the astonishment of many persons who attended.

Locality, or the connection of our ideas with places, as we are informed by the anonymous author, whose treatise we have cited, is made the foundation of this system. In this respect, it is analogous to the scheme of mnemonics practised by the ancients, but it is here applied much more extensively and advantageously than it was by them. How far it deserves this commendation, the reader who is desirous of farther information concerning it will be informed by consulting the treatise already quoted; in which, as we conceive, there is a just developement of the principles of M. Feinaigle; but the detail is so extensive and so incapable of abridgment, that it would be inconsistent with our limits to enlarge, so as to give any satisfaction to our readers. The general principle of this art is that of dividing walls and houses into different compartments, and annexing numbers to them in a particular order, or words together with the numbers; the recollection of these words being assisted by associating some idea of relation between the objects and their situation. Consonants are also annexed to the figures, which letters are not merely arbitrary, but adapted as nearly as possible to the form of the figures. These letters, and the figures which they are intended to represent, should be impressed strongly on the memory, as the consonants must be converted into words by the introduction of vowels. To each word should be affixed some striking idea; and the objects that are selected, each of which is expressed by a word, must be arranged in different places, beginning with the floor, and proceeding to the first, second, and third wall, &c. Having divided a room into parts, as the floor and walls, subdivided these into places, changed figures into letters, and formed words, we shall by these means be enabled to remember a series of figures or things. For this purpose, it would be advantageous to fix upon some room to which we have been accustomed. If this room should have been hung with pictures, engravings or plans, or ornamented with busts, &c. the remembrance of places, or localities, will be facilitated. The order of things in a room will be familiar to us. The squares or places may be filled with some pictures of our own drawing, and it will be as easy to remember the symbols, or hieroglyphics, as to remember the situation or place of any picture, or article of furniture in a room. By supposing the floor to be constructed of mosaic, instead of being covered with a carpet, we shall have spaces for symbols. The outlines of the symbols are intended to represent, as accurately as possible, the various figures in the two rooms, to which our plan extends, so that they may be permanently fixed in our memory. How these symbols are made applicable to chronology, history, &c. requires a more diffuse detail than our limits will allow. Having already given our opinion of the various artifices that have been devised for aiding the memory, it is needless to enlarge. The reader will perceive that it must require time and labour, and no inconsiderable exertion of memory, to derive any advantage from mechanical modes of aiding the exercise of it.

Under the article MEMORY, we have given some examples of extraordinary retentiveness in the use of this faculty. To those already mentioned, we shall here add some others. See AVICENNA, FULLER, JEWEL, and SCALIGER.

Lipsius remembered the whole history of Tacitus, and pledged himself to recite it word by word, or any passage that might be required. Francis Suarez could repeat all St. Augustine's works by heart, alleging particular lines and words, with the volume and page in which they occurred. Magliabecchi had a surprising memory. A gentleman who wished to try it, lent him a MS. which he was going to print, and soon after it was returned, the author came to him with a melancholy aspect, and pretended it was lost. Magliabecchi being requested to recollect as much of it as he could, wrote the whole without missing a word, or making any variation in the spelling. We have mentioned some extraordinary instances of the power of memory possessed by Jedediah Buxton under his article. Without the assistance of pen, ink, chalk, or any other mark, he could multiply five or six figures by as many, or divide as large sums off hand, in less time than the most expert arithmeticians could perform their operations. Being asked how many cubical $\frac{1}{8}$ths of an inch were contained in a body, whose three sides were 23145789 yards, 5641732 yards, and 54965 yards; after about five hours, in the midst of more than 100 of his fellow labourers, he computed the result; and gave it in a line of 28 figures, without the least hesitation or mistake. He would repeat his answers to difficult questions a month or two after he had solved them. Of his own accord he calculated how much one farthing doubled 140 times would amount to; and the answer was set down from his lips in 39 places of pounds, and an odd 2*s*. 6*d*. Being once asked how many barley corns would reach eight miles; he answered, in $1\frac{1}{2}$ minute, 1520640 barley corns. In 13 minutes he computed, that the distance of York from London, being 204 miles, a coach-wheel, whose circumference was six yards, would turn round in that interval 59,840 times. By the strength of his memory he multiplied 39 figures by 39 figures, and had no recourse to pen, ink, or paper.

At the moment of writing this article, the editor is informed of a boy, from Vermont in America, not eight years of age, who performs wonders in extempore calculation. The rapidity and correctness with which he multiplies and divides large numbers, with which he finds all the factors of a composite number, and whether any number proposed be prime or not, and with which he solves a variety of arithmetical questions that are proposed to him, are truly astonishing.

The editor has been favoured by F. Baily, esq. of Gray's Inn, an eminently competent judge of those performances in which this boy excels, with the following account. His name is Zerah Colburn. He was born at Cabut, a town lying at the head of Onion river, in Vermont, America, on the 1st of September 1804. He began to manifest his extraordinary powers in August 1810, when he was not six years of age; though he had derived no other advantage from education beyond what was to be obtained at a small school in a remote part of the country. On the 12th of May 1812 he arrived in this country, and has since exhibited his astonishing performances to a great number of spectators, and before many persons of the first eminence for mathematical and philosophical knowledge.

At a meeting of his friends, which was held for the purpose

pose of concerting the best method of promoting the views of the father, this child undertook, and completely succeeded in, raising the number 8 progressively up to the sixteenth power; and in naming the last result, *viz.* 281,474,976,710,656, he was right in every figure. He was then tried as to other numbers, consisting of one figure; all of which he raised (by actual multiplication and not by memory) as high as the tenth power, with so much facility and dispatch, that the person appointed to take down the results was obliged to enjoin him not to be so rapid. With respect to numbers consisting of two figures, he would raise some of them to the sixth, seventh, and eighth power; but not always with equal facility: for the larger the products became, the more difficult he found it to proceed. He was asked the square root of 106929; and before the number could be written down, he immediately answered 327. He was then required to name the cube root of 268,336,125; and with equal facility and promptness he replied 645. Various other questions of a similar nature, respecting the roots and powers of very high numbers, were proposed by several of the gentlemen present; to all of which he answered in a similar manner. One of the party requested him to name the factors which produced the number 247483, which he immediately did by mentioning the two numbers 941 and 263; which indeed are the only two numbers that will produce it. Another of them proposed 171395, and he named the following factors as the only ones that would produce it; *viz.* 5×34279, 7×24485, 59×2905, 83×2065, 35×4897, 295×581, and 413×415. He was then asked to give the factors of 36083; but he immediately replied that it had none; which in fact was the case, as 36083 is a prime number. Other numbers were indiscriminately proposed to him, and he always succeeded in giving the correct factors, except in the case of prime numbers, which he discovered almost as soon as proposed. One of the gentlemen asked him how many minutes there were in forty-eight years; and before the question could be written down, he replied 25,228,800: and instantly added, that the number of seconds in the same period was 1,513,728,000. Various questions of the like kind were put to him; and to all of them he answered with nearly equal facility and promptitude; so as to astonish every one present, and to excite a desire that so extraordinary a faculty should, if possible, be rendered more extensive and useful.

Being asked to inform the gentlemen present how he was enabled to answer, with such facility and correctness, the questions that were proposed to him, he declared that he did not know how the answers came to his mind. It was observed, however, that the child performed his several operations by some rules known only to himself. The discovery was made in one or two instances, when he had been closely pressed upon that point. In one case he was asked to tell the square of 4395; he at first hesitated, fearful that he should not be able to answer it correctly: but when he applied himself to it, he said it was 19,316,025. On being questioned as to the cause of his hesitation, he replied that he did not like to multiply four figures by four figures: but, said he, "I found out another way; I multiplied 293 by 293, and then multiplied this product twice by the number 15, which produced the same result." On another occasion, his highness the duke of Gloucester asked him the product of 21,734 multiplied by 543: he immediately replied 11,801,562: but, upon some remark being made on the subject, the child said that he had, in his own mind, multiplied 65202 by 181. Now, although in the first instance it must be evident to every mathematician that 4395 is equal to 293×15, and consequently that $(4395)^2 = (293)^2 \times (15)^2$; and further, that in the second case 543 is equal to 181×3, and consequently that $21734 \times (181 \times 3) = (21734 \times 3) \times 181$; yet, it is not the less remarkable that this combination should be immediately perceived by the child, and we cannot the less admire his ingenuity in thus seizing instantly the easiest method of solving the question proposed to him.

Amongst a variety of cases of this kind, the following singular instance is particularly worthy of being recorded. He was asked to tell the square of 999999: which, after some little time, he stated to be 999,998,000,001; and he further observed, that he had produced this result by multiplying the square of 37037 by the square of 27. He then, of his own accord, multiplied that product by 49; and said that the result (*viz.* 48,999,902,000,049) was equal to the square of 6,999,993. He afterwards multiplied this product by 49; and observed that the result (*viz.* 2,400,995,198,002,401) was equal to the square of 48,999,951. He was again asked to multiply this product by 25; and in naming the result (*viz.* 60,024,879,950,060,025), he said that it was equal to the square of 244,999,755. These astonishing efforts of his mind require no comment; and sufficiently shew that he possesses a more intimate knowledge of the science of numbers than can be obtained by the ordinary, or even more abstruse rules of arithmetic.

It is well known to mathematicians, that Fermat had asserted that $2^{32} + 1 = 4,294,967,297$ was a prime number; but Euler detected that error, by discovering that it was equal to $6,700,417 \times 641$. The same number was proposed to this child, who (after a lapse of some weeks) found out the factors by the mere operation of his mind: and the method which he took to obtain his object, clearly shewed that he had not derived his information from any other source.

MNEMOSILLA, in *Botany*, a genus of Forskall's, which, according to Jussieu, is the same as HYPECOUM. See that article.

MNEMOSYNE, in *Mythology*, was the daughter of Cœlus and Terra, according to the theogony of Hesiod; and Jupiter being enamoured of her, made her mother to the nine Muses. To Mnemosyne is ascribed, according to Diodorus Siculus, the art of reasoning, and giving suitable names to every being, so that we can describe them, and converse about them without seeing them. Mnemosyne is generally allowed to have been the first who used helps for the memory, and this is intimated in her name.

MNETHEL, in *Geography*, a town of Persia, in the province of Chusistan; 102 miles E. of Suster.

MNEVIS, in *Mythology*, the name of a sacred bull, consecrated to the sun, and worshipped by the Egyptians at Heliopolis. The worship of Mnevis gradually disappeared, when Apis became the general deity of the country. From the era in which Cambyses overthrew the magnificent temple of Heliopolis, we may date the downfall of the worship of Mnevis. This Mnevis was, according to Bryant, a compound of Men-neuas, the lunar god Nevas, the same as Noas, or Noah. The name relates to the same person who, in Crete, was styled Minos; and the same also who was represented under the emblem of the Men-taur or Mino-taurus. Ant. Myth. vol. ii. p. 416, &c.

MNIARUM, in *Botany*, so called from μνιαρος, *mossy*, in allusion to its habit. Forst. Gen. 1. t. 1. Linn. Suppl. 18. Schreb. 9. Willd. Sp. Pl. v. 1. 30. Mart. Mill. Dict. v. 3. Juss. 441. Brown Prodr. Nov. Holl. v. 1. 412. Labill. Nov. Holl. v. 1. 8. (Ditoca; Gærtn. t. 126.)—Class and order, *Monandria Digynia*. Nat. Ord. *Holeraceæ*, Linn. *Atriplices*, Juss. *Chenopodiis affinia*, Brown.

Gen. Ch. *Cal.* Perianth inferior, pitcher-ſhaped, permanent, cut half way down into four equal, erect, obtuſe, rigid ſegments. *Cor.* none. *Stam.* Filament one, capillary, erect, inſerted into the mouth of the calyx, ſcarcely longer than its ſegments; anther roundiſh, furrowed. *Piſt.* Germen ſuperior, oval; ſtyles two, thread-ſhaped, gradually divaricated, the length of the ſtamen: ſtigmas ſimple. *Peric.* none. *Seed* ſolitary, ſmall, oblong, with a membranous coat, encloſed in the hardened tube of the calyx.

Eſſ. Ch. Calyx pitcher-ſhaped, four-cleft. Corolla none: Seed one, encloſed in the tube of the calyx.

Akin to *Scleranthus*, from which it differs in the ſtamen being, for the moſt part, ſolitary; the calyx four-cleft; and the ſtalks two-flowered, with four bracteas at the ſummit. The ſeed in both genera is inverted, the embryo curved round the albumen, the radicle ſuperior. *Brown.*

1. M. *biflorum.* Linn. Suppl. 81. Forſt. Prodr. 2. Comm. Goett. v. 9. 19. t. 1. (M. pedunculatum; Labill. Nov. Holl. v. 1. 8. t. 2. Ditoca muſcoſa; Gærtn. v. 2. 196. t. 126. f. 1.)—Stem tufted. Branches very ſmooth. Leaves finely toothed at the baſe only, ſhorter than the fruit-ſtalks. *Br.*—Native of New Zeeland, Terra del Fuego, and Van Diemen's land. The *ſtems* compoſe denſe maſſy tufts, varying in height, with the aſpect of a *Minuartia.* Every part of the herb is ſmooth. *Leaves* oppoſite, awl-ſhaped, united and finely toothed at the baſe; otherwiſe entire. *Flower-ſtalks* axillary, ſolitary, ſimple, at firſt ſhort, but ſubſequently elongated beyond the leaves; each bearing a pair of minute ſeſſile greeniſh *flowers*, accompanied by four little ovate *bracteas.* The *calyx* of the fruit is hardened, tumid, ovate, cloſed about the ſeed, and crowned with its own little permanent ſegments.

2. M *faſciculatum.* Br. n. 2.—"Stems procumbent, branched. Branches minutely downy. Leaves finely toothed throughout. Fruit-ſtalks ſcarcely ſo long as the leaves."—Gathered by Mr. Brown in Van Diemen's land.

MNIUM, a word adopted by Dillenius from the Greeks, whoſe μνιον is ſynonymous with Moſs. He therefore choſe it for one of his own genera of Moſſes, the character of which is to have two different kinds of heads, or fructification; the one powdery and naked, that is, deſtitute of calyx as well as of capſule; the other of the ſame capſular nature as in *Bryum* and *Hypnum.* Conſidering this character as ſufficient to diſtinguiſh *Mnium* from all other Moſſes, he proceeds to inquire into the nature of theſe different parts of fructification. In his concluſion he miſtakes the male for the female, though his error has not commonly been obſerved, becauſe he terms capſule what he believed to be the anther, but which is indeed the capſule, properly ſo called. (See Dillenius and Musci.) We therefore now reſume the language, though we diſcard the ideas, of this eminent writer.

Dillenius, conſidering every moſs as a *Mnium* in which he met with a powdery head, although he did not detect the capſule, has made eight ſpecies; but this principle has widely miſled him. His fifth and ſixth ſpecies are *Jungermanniæ*, his ſeventh is the *Blaſia puſilla*, previouſly well defined, as a diſtinct genus, by Micheli. In the reſt of his ſpecies, Dillenius is as correct as any perſon could, at that time, be.

Linnæus, following up the principle he had adopted from Dillenius, referred to *Mnium* every moſs, with a terminal fruit-ſtalk, in which the powdery head of male flowers, ſuppoſed by them female, had been obſerved. As his followers proceeded to look more and more cloſely into the ſtructure of theſe minute vegetables, the powdery heads, or ſtars, as they were termed when ſurrounded by leaves, were diſcovered in many ſpecies, hitherto referred to *Bryum.* Nor is this wonderful, for the diſcoveries of Hedwig have proved them eſſential to every moſs, they being unqueſtionably the male flowers. For a long time botaniſts were perpetually diſputing, whether to refer particular ſpecies to *Mnium* or *Bryum*, according as they had met with the powdery head or not. Hudſon alone has ſhewn his judgment, in conſidering the naked or leafleſs head as proper to the former; by which, except the original blunder reſpecting two or three *Jungermanniæ*, he has preſerved himſelf from error. Hedwig has confuſed the ſubject by reverſing the original characters. His *Bryum* has a round or capitate male flower, or powdery head; his *Mnium* a flat or diſcoid one. This leads to no natural character. Indeed the difference itſelf is uncertain, the part in queſtion varying in convexity at different periods of growth. The ableſt botaniſts who have in general followed Hedwig, as Schreber, Swartz, and Roth, well aware of his miſtake in this inſtance, thought to correct it, by uniting the two genera into one, under the name of *Bryum.* Hoffmann, more boldly but leſs ſucceſsfully, recurred to the fringe alone, making almoſt every terminal-fruited moſs with a ſingle fringe *Bryum*, with a double one *Mnium.* See Fringe *of Moſſes.*

The writer of the preſent article at length propoſed to diſtinguiſh *Mnium* by the longitudinal furrows of its capſule, which in another double-fringed genus, *Bartramia*, had been found a certain and clear mark of difference. This character keeps the original real *Mnia* of Dillenius together, except the firſt, which is the *Tetraphis pellucida*; and has the advantage of aſſociating with them moſt naturally the *Arrhenopterum* of Hedwig, a genus whoſe diſtinction was founded by its author on the axillary, not terminal, male flowers; a character which the ſlighteſt attention to moſſes will ſhew to be of no importance, as to generic diſcrimination. *Mnium* is therefore now defined as follows. Tr. of Linn. Soc. v. 7. 261. Fl. Brit. 1344.

Eſſ. Ch. Capſule cylindrical, at length furrowed. Outer fringe of ſixteen tapering teeth; inner a laciniated membrane. Veil ſmooth. Flowers terminal.

The furrows are always ſixteen, being equal in number to the teeth of the outer fringe, and indeed to the principal ſegments of the inner one. Six ſpecies are defined in the Tranſactions of the Linnæan Society above quoted.

1. M. *androgynum.* Narrow-leaved Spring-moſs. Linn. Sp. Pl. 1574. Sm. Fl. Brit. 1344. Engl. Bot. t. 1238. Hedw. Theor. 149. t. 12. f. 48—50. (M. peranguſtis et brevibus foliis; Dill. Muſc. 230. t. 31. f. 1. Bryum androgynum; Hedw. Sp. Muſc. 178. Turn. Muſc. Hib. 11.)—Monoecious. Capſule ſtraight. Lid conical. Leaves imbricated every way, ſpreading; toothed at the point.—Native of moiſt ſhady boggy places throughout Europe, flowering in March. The capſules, which ripen in April or May, are very rare. The *ſtems* form denſe perennial tufts, and are branched, clothed with bright green, dotted, pellucid, lanceolate, ſingle-ribbed, acute leaves; toothed towards the point; entire and revolute below. *Flowers* terminal; the male in little round ſtalked heads; female on the ſame plant, ſeſſile. *Capſule* nearly upright, on a ſhining red ſtalk an inch long. *Lid* ſhort, conical, blunt, ſtriated, a little curved.

2. M. *conoideum.* Club-fruited Spring-moſs. Sm. Fl. Brit. 1345. Engl. Bot. t. 1239. (Bryum conoideum; Dickſ. Crypt. faſc. 4. 9. t. 11. f. 2. Turn. Muſc. Hib. 112. Grimmia? Forſteri; Sm. Fl. Brit. 1196. Engl. Bot. t. 2225. Bryum Forſteri; Dickſ. Crypt. faſc. 3. 4. t. 7. f. 8.)—Monoecious? Capſule ſtraight, obovate. Lid awl-ſhaped. Leaves imbricated every way, ſpreading, entire.—Native of the

the trunks of trees in Scotland and Ireland, but rare. Smaller than the former. The *ſtems* compoſe ſmall, convex, perennial patches, and are moſtly ſimple, leafy, half an inch high. *Leaves* oblong, entire, pale green, ſingle-ribbed, pointleſs, dotted juſt as in the foregoing. *Male flowers* unknown. *Fruit-ſtalks* ſolitary, terminal, half an inch high. *Capſule* obovate, with a curved lid, of nearly its own length. The more we conſider the matter, the leſs doubt have we reſpecting the above ſynonyms.

3. M. *paluſtre*. Greater Forked Spring-moſs. Linn. Sp. Pl. 1574. Sm. Fl. Brit. 1346. Hedw. Sp. Muſc. 188. Schmidel. Ic. 218. t. 56. f. 2. (M. majus, ramis longioribus bifurcatis; Dill. Muſc. 233. t. 31. f. 3, 4. Bryum paluſtre; Engl. Bot. t. 391. Turn. Muſc. Hib. 113.)—Dioecious. Capſule oblique. Lid conical. Leaves acute; the upper ones curved to one ſide. Stem erect, forked.—Native of bogs, about mountain rivulets, and in various watery ſituations throughout Europe; flowering in April and May; fruiting in June and July. The *ſtems* are three or four inches high. *Leaves* of a light yellowiſh-green, lanceolate, acute, channelled, ſingle-ribbed, entire; wavy when dry. *Male flowers* like a broad diſk, ſurrounded with radiating leaves; often proliferous, throwing up ſtalked round heads, like the male flowers of the firſt ſpecies; *female* ſeſſile. *Fruit-ſtalks* ſolitary between the new ſhoots of the ſeaſon, two or three inches high, wavy, red below. *Capſule* curved, with a ſhort conical lid.

4. M. *reclinatum*. Procumbent American Spring-moſs. Sm. Tr. of Linn. Soc. v. 7. 262. (M. ramis brevibus, inordinatè progredientibus; Dill. Muſc. 239. t. 31. f. 8.) —Dioecious. Capſule nearly erect. Lid conical. Leaves bluntiſh, rather turned one way. Stem procumbent, much branched.—Gathered by Mitchell in bogs in Virginia. *Dillenius*. Its colour and habit are like the laſt, but the ſize only half as great. *Capſule* ſlender, nearly erect. *Stem* much branched, not forked. *Male flowers* ſtalked, naked.

5. M. *pendulum*. Pendulous-fruited Spring-moſs. Sm. n. 5.—Capſule pendulous. Lid nearly flat. Leaves awl-ſhaped, ſtriated, recurved. Stem erect.—Gathered by Mr. Menzies, in New Zeeland. *Stems* determinately branched, leafy, clothed with ruſty down, like many moſſes that grow in clear ſprings. *Leaves* yellowiſh, ſingle-ribbed, imbricated every way, but recurved, chiefly toward one ſide. *Fruit-ſtalks* red, two inches high. *Capſule* cylindrical, or ſomewhat bell-ſhaped, cheſnut-coloured. *Lid* flat, with a central knob.

6. M. *arrhenopterum*. Axillary Spring-moſs. Sm. n. 6. (Arrhenopterum heteroſtichum; Hedw. Sp. Muſc. 198. t. 46. f. 1—9. Bryum heteropterum pellucidum; Dill. Muſc. 352. t. 45. f. 11; but indifferent. B. foliis membranaceis obtuſis; Dill. Muſc. 552. t. 35. f. 19; better; both determined by the Dillenian herbarium. Hypnum illecebrum; Linn. Sp. Pl. 1594; excluding the ſynonym of Dillenius. Fl. Lapp. ed. 2. 329.)—Capſule inclining. Lid awl-ſhaped. Leaves elliptical, obtuſe. Stem erect. Native of Virginia, Pennſylvania and Lapland.—*Stems* about two inches high, branched. *Leaves* imbricated, pale whitiſh-green, elliptical, concave, ſhining, ſingle-ribbed, ſerrated at the end. *Fruit-ſtalks* an inch long, ſtraight, rather ſtout. *Capſule* curved, with a beaked red lid.

There appear to be ſeveral ſpecies ſtill referrible to this genus, which are not as yet any where deſcribed.

MO, in *Geography*, a town of Sweden, in Helſingland; ſix miles W. of Soderhamn.

MOA, an iſland in the Eaſt India ſea, about 30 miles long and 10 broad. S. lat. 8° 21′. E. long. 127° 45′.

MOAB, *Land of*, or MOABITIS, ſo called from Moab one of the inceſtuous ſons of Lot, in *Ancient Geography*, was ſituated in Arabia Petræa, on the north of Midian, having the river Arnon on the weſt, which divided it all the way from the tribe of Reuben, the Iſhmaelites on the eaſt, and the land of Gilead on the north. Their country was at firſt inhabited by the gigantic Emims, whom they expelled, making themſelves maſters of it, and of all its cities, which were both numerous and conſiderable. Some of theſe cities, mentioned by Joſephus, were on the other ſide of the Arnon, and therefore not ſo properly in Moabitis, as in the land of the Amorites, or Reubenites; particularly Heſhbon; but they might have been inhabited by the Moabites. The limits of this country, indeed, were continually fluctuating; ſo that we read of the plains of Moab, called alſo by Moſes the land of Moab; but which had been taken by Sihon, quite as far as the river above mentioned. Mount Nebo is placed by Moſes in the land of Moab, though ſeated on the other ſide of the Arnon, in the kingdom of Sihon. This river, however, ſeems to have been the proper northern boundary between theſe two kingdoms, as Moab ſeems to have been the ſouthern boundary between Arabia Petræa and Deſerta. See MOABITES.

MOAB, in *Geography*, a town of Arabia, in the province of Hadramaut; 83 miles W. of Hadramaut.—Alſo, a town of Arabia Felix, in the province of Yemen, and reſidence of the prince, built in 1708, and ſituated between Damar and Sanaa.

MOAB, or *El-Raba*, a town of Syria; 50 miles S.E. of Jeruſalem.

MOABITES, in *Ancient Hiſtory*, the deſcendants of Moab, the ſon of Lot, by his eldeſt daughter. The poſterity of Lot ſettled in the country bordering on the mountain, where he was born, which ſome make part of Cœleſyria, while others allege that it belongs to Arabia; and having driven out the old inhabitants, they poſſeſſed a ſmall tract called Moabitis, or the land of Moab. (See MOAB.) They were governed by kings, practiſed circumciſion, and employed themſelves moſtly in paſturage and breeding cattle, which conſtituted their chief wealth. It is probable that their language was a dialect of the Canaanitiſh or Hebrew. They had once the knowledge of the true God, and retained it till the time of Moſes, even after they had very much corrupted their religion by introducing the worſhip of falſe gods. The idols of the Moabites, mentioned in ſcripture, were Chemoſh and Baal-Peor. Some ſuppoſe that theſe were different names of the ſame idol: but others think that Baal-Peor was Bacchus, and Chemoſh ſeems to have been a different idol. In the practice of their religious rites, they ſacrificed both in the open air, on mountains dedicated to that ſervice, and in temples built for their idols in the cities: beſides oxen and rams, they offered on extraordinary occaſions human victims, according to the Phœnician cuſtom.

The firſt inhabitants of the country were a gigantic race, called Emims, or Terribles, probably deſcendants of Ham. Theſe were expelled by the Moabites; but the latter in proceſs of time loſt that part of their land which lay to the N. of the river Arnon. When the Iſraelites, after the death of Othniel, returned again to idolatry, Eglon, king of Moab, was an inſtrument in puniſhing them; he invaded Iſrael and kept the Iſraelites in ſubjection eighteen years. Ehud, having ſecretly put Eglon to death, was obliged to make his eſcape beyond Jordan; and there he aſſembled a body of forces, who attacked the Moabites, and ſlew 10,000 of their beſt men. By this diſaſter the power of the Moabites was broken, and the Iſraelites were freed from the yoke of of that nation. Notwithstanding the protection which the king of Moab afforded to the parents of David and to David himself, when he was persecuted by Saul, as soon as he came to the crown the Moabites entered into a confederacy against him; but in consequence of a signal victory which he obtained over them, many of them were put to the sword, and the rest became his vassals and tributaries. From this time they continued subject to Solomon and Rehoboam, until the revolt of the ten tribes, upon which they became tributaries to the kings of Israel, though they had kings of their own, who were little better than viceroys. After the death of Ahab, Mesha, king of Moab, rebelled against his son Ahaziah, but the short reign of this prince not permitting any attempt to reduce him, his brother and successor Jehoram, assisted by Jehoshaphat, king of Judah, and the king of Edom, his tributary, made an expedition for this purpose; the result of which was, the defeat of the Moabites and the devastation of a great part of their country. It was not long before the Moabites, entering into an alliance with the Ammonites, the Edomites of mount Seir, and other neighbouring nations, attempted to revenge the losses they had sustained in this invasion of their country on Jehoshaphat, king of Judah, who had encouraged Jehoram to undertake it. Their attempt proved unsuccessful, and terminated in their total ruin. After this period the Moabites do not seem to have disturbed Israel for many years. On the declension of the kingdom of Israel, they seem to have retaken from the tribes of Reuben and Gad a great part of the land which formerly belonged to them, before the invasion of Sihon; but elated by their success, they behaved with pride and insolence, in consequence of which several of the ancient prophets, and Isaiah in particular, threatened them with utter destruction. After the dreadful discomfiture of the army of Sennacherib, the son of Shalmaneser, the Moabites often revolted from his successors, and were as often reduced, till they were entirely subdued by Nebuchadnezzar; but upon Nebuchadnezzar's departure from Judea and Syria, after his second expedition into these parts, they, with the other neighbouring nations, proposed to Zedekiah to enter into a league against the Chaldæans, to which that prince consented, on the accession of the Egyptians to their confederacy; but this measure, adopted by Zedekiah against the remonstrance of the prophet Jeremiah, became the occasion of his utter ruin; for his new allies deserted him in his distress. From this period history makes little mention of the Moabites, who became subject to the great empires, and at length coalesced as one people with the neighbouring nations which inhabited the deserts of Syria; so that, although Josephus mentions the Moabites as a distinct nation long after, observing that they were subdued by Alexander Jannæus, king of the Jews, and that in his time they were a numerous nation; yet, in the third century after Christ, they had lost their ancient name, and were comprehended under the more general denomination of Arabians. Anc. Un. Hist. vol. i.

MOAGANORE, in *Geography*, a town of Hindoostan, in Golconda; 10 miles N.W. of Rachore.

MOAGAS, a cluster of small islands in the Caribbean sea, near the coast of South America, at the entrance of the gulf of Venezuela: they are eight or nine in number, extending from north to south, and but one excepted, low, flat, and covered with trees. The southernmost is the largest.

MOAMAA, a port and good harbour of Nubia, in the Red sea; 15 miles S. of Aidab.

MOANESS, a cape on the N. coast of the island of Shetland. N. lat. 60° 44′. W. long. 1° 32′.

MOANGUNGE, a town of Bengal; 72 miles N.N.W. of Dacca.

MOAR, a town of Hindoostan, in Bahar; 22 miles N.E. of Bahar.

MOAR-LOVRE, in *Agriculture*, a term made use of by some to express a peculiar distemperature of corn, a sort of blight. In this case the earth is said to sink away from the roots of the corn, and to leave the plants standing in a great part above the ground with naked roots; which are too weak to support the stalks: the plants, of course, fall down, and the ears become light. It is a distemper peculiar to corn growing on light and loose lands, which Mr. Tull has mentioned in his Horse-hoeing Husbandry. And it is supposed that the best remedy is to bring up mould against the rows, when they are strong enough to bear it, and it is fine and dry; the motion of the stalks with the wind draws in this loose powdery mould, and it spreads equally, settles about the roots, and covers them so as to produce fresh nourishment and support.

MOAT, in *Fortification*, a deep trench dug round a town or fortress to be defended, on the outside of the wall, or rampart. See *Plate* VII. *Fortif. fig.* 1. *lit. b, b, b,* &c.

The depth and breadth of a moat often depend on the nature of the soil; according as it is marshy, rocky, or the like. The brink of the moat next the rampart in any fortification is called the *scarp*, and the opposite one the *counterscarp*. See DITCH.

MOAT, *Dry*, is that which is destitute of water: this ought to be deeper than one which is full of water.

MOAT, *Lined*, is that whose scarp and counterscarp are cased with a wall of mason's work lying aslope.

MOAT, *Flat-bottomed*, is that which hath no sloping, its corners being somewhat rounded.

MOAT, *Angle of the*. See ANGLE.

MOATAZALITES, MOTAZALITES, or *Separatists*, a religious sect among the Turks, who deny all forms and qualities in the divine Being: or who divest God of his attributes.

There are two opinions among the Turkish divines concerning God. The first admits metaphysical forms, or attributes; as, that God has wisdom, by which he is wise; power, by which he is powerful; eternity, by which he is eternal, &c.

The second allows God to be wise, powerful, eternal; but will not allow any form or quality in God, for fear of admitting a multiplicity.

Those who follow this latter opinion are called *Moatazalites*: they who follow the former, *Sephalites*.

The Moatazalites also believed that the word of God was created *in subjecto*, as the schoolmen term it, and to consist of letters and sound; copies thereof being written in books to express or imitate the original; they denied absolute predestination, and affirmed that man is a free agent. They held that if a professor of the same religion be guilty of a grievous sin, and die without repentance, he will be eternally damned, though his punishment will be lighter than that of the infidels. Moreover, they denied all vision of God in paradise by the corporeal eye, and rejected all comparisons or similitudes applied to God. This sect is said to have first invented the scholastic divinity, and is subdivided into no less than twenty inferior sects, which mutually brand one another with infidelity. Of these the most remarkable are the Hodeilians, the Jobbaians, the Hashemians, the Nodhamians, the Hayetians, the Jahedhians, the Mozdarians, the Bacharians, the Thamamians, and the Kadarians. Sale's Prelim. Disc. p. 159, &c.

MOATE, or MOATE GRENOGUE, in *Geography*, a post-town,

town, or rather village in the county of Weſtmeath, Ireland. It is 52 miles W. by N. from Dublin, and 7½ from Athlone.

MOAWIYAH, in *Biography*, ſixth caliph of the Arabians, was the ſon of Abu Sofian, a chief of Koreiſh, and an eminent commander under Mahomet. Moawiyah was appointed ſecretary to the prophet, an office which he filled for ſeveral years, but after the conqueſt of Syria, he was made governor of the province of Omar, and was continued in that high ſtation by Othman. He obtained great ſucceſs againſt the Greek emperors, and, in 654, he conquered the iſle of Rhodes, and demoliſhed the famous coloſſus of the ſun. In the following year he became a competitor for the caliphate, but Ali was elected; Moawiyah inſtantly declared againſt him, and prevailed upon Amru to join him. He was proclaimed caliph at Mecca and at Medina, and maintained a civil war againſt Ali, till the aſſaſſination of that caliph in 660. Moawiyah was, at the ſame time, ſeverely wounded by one of the three conſpirators who undertook to reſtore peace among the Muſſulmans by the aſſaſſination of the two rivals, but he eſcaped with his life. At firſt, Haſſan, Ali's ſon, oppoſed the pretenſions of Moawiyah, but ſoon reſigned his power to his opponent, who obtained the caliphate without a rival in 661, being the firſt prince of the dynaſty of the Ommiyans. An inſurrection of the Kharegites was one of the firſt events of his reign, which was quelled by the people of Irak, with the total extermination of the ſect. A reconciliation with his illegitimate brother Ziyad, a man of great talents, who had taken the part of Ali, and was made governor of Perſia, added great ſtrength to the throne of Moawiyah, who, to gain him, did not ſcruple to violate the laws of the Koran, by acknowledging him as the blood of the Koreiſh, though his legal father was a Greek ſlave. The temper and ſeverity of Ziyad was of great ſervice in ſuppreſſing ſome commotions which threatened to diſturb the peace of the empire. In 668, Moawiyah ſent his ſon Yezid with an army to beſiege Conſtantinople, but the undertaking was beyond the Muſſulman power, and after ſpending ſeven years in a ſeries of repeated ſummer attacks, attended with a variety of petty events, but ſignalized by no great action, they relinquiſhed the enterprize. The caliph's arms were more ſucceſsful in another quarter, and obtained for him the complete poſſeſſion of Samarcand. Moawiyah fixed his reſidence at Damaſcus, and the great object of his latter years was to ſecure the crown to his ſon Yezid, who was by no means fitted for the high rank to which he aſpired. Moawiyah, after a long ſtruggle with the people, procured the public recognition of Yezid as his own colleague, and preſumptive heir to the caliphate. In a very ſhort time after this he expired at Damaſcus, after a reign of about twenty years, and when he had attained to the age of ſeventy-five. He was, ſays his biographer, the moſt eminent of the Saracen caliphs, and extolled for his capacity, courage, generoſity, and clemency. He was the firſt of the caliphs who wore rich garments, and affected royal ſplendour. He was a patron of learning, particularly of thoſe who were proficients in poetry. Univer. Hiſt.

MOBARACGUNGE, in *Geography*, a town of Hindooſtan, in Oude; 14 miles W. of Fyzabad.

MOBAS, a town of New Mexico, in the province of Hiaqui; 25 miles S.E. of Riochico.

MOBILE, Moveable, any thing ſuſceptible of motion, or that is diſpoſed to be moved either by itſelf, or by ſome other prior mobile, or mover.

Mobile, *Primum*, in the *Ancient Aſtronomy*, was a ninth heaven, or ſphere, imagined above thoſe of the planets, and fixed ſtars.

This was ſuppoſed to be the firſt mover, and to carry all the lower ſpheres round along with it; by its rapidity communicating to them a motion by which they revolved in twenty-four hours. But the diurnal revolution of the planets is now accounted for, without the aſſiſtance of any ſuch primum mobile.

Mobile, *Perpetuum*. See *Perpetual* Motion.

Mobile, in *Geography*, a large, navigable river of America, formed by two main branches, the Alabama, and the Tombeckbee, in the S.W. part of Georgia, juſt below a conſiderable iſland, the S. point of which is in about N. lat. 31° 26′, and W. long. 87° 55′. Purſuing a S. courſe into Weſt Florida, the confluent ſtream enters the gulf of Mexico at Mobile Point in N. lat. 30° 17′, 11 leagues below the town of Mobile. Large veſſels cannot approach the town within the diſtance of ſeven miles: the breadth of the bay is in general about three or four leagues. Alligators of a large ſize and in great number baſk on the ſhores, as well as ſwim in the rivers and lagoons. The courſe of this river from the N.E. ſource of the waters of the Alabama to Mobile Point is eſtimated at about 460 miles. Large boats can navigate 350 miles, and canoes much farther.

Mobile, a city of Weſt Florida, formerly important and ſplendid, but now in a ſtate of decline. Its figure is oblong, and it is ſituated on the W. bank of the river. The bay of Mobile terminates a little to the N.E. of the town in marſhes and lagoons, which ſubject the inhabitants to fevers and agues in the hot ſeaſon. The town contains ſeveral elegant houſes, occupied by French, Engliſh, Scotch, and Iriſh. Fort Conde, ſituated near the bay, towards the lower end of the town, is a regular fortreſs of brick; and there is a neat ſquare of barracks for the officers and ſoldiers. Mobile, when poſſeſſed by the Engliſh, ſent yearly to London ſkins and furs to the value of from 12 to 15,000*l.* ſterling. It ſurrendered to the Spaniſh forces in 1780.

Mobile, *Mobiles*, plural, in the *Ancient Greek Muſic*, the moveable or central ſounds of each tetrachord, ſuch as were tuned differently in different genera; whereas the two extremes, or the loweſt and higheſt ſound of each genus, were fixt: *ſoni ſtantes*. See Tetrachord, Genus, and Sound.

MOBILIA Bona, in the *Civil Law*, are what in common law, &c. we call *moveables*, or *moveable goods*.

MOBILITY, in the *Schools*, &c. an aptitude or facility to be moved.

The hypotheſis of the mobility of the earth is the moſt plauſible; and is that univerſally admitted by the later aſtronomers. Pope Paul V. appointed commiſſioners to examine the opinion of Copernicus touching the mobility of the earth. The reſult of their enquiry was, a prohibition to aſſert, not that the mobility was poſſible, but that it was actually true: that is, they allowed the mobility of the earth to be held as an hypotheſis, which gives an eaſy and ſenſible ſolution of the phenomena of the heavenly motions; but forbad the mobility of the earth to be maintained as a theſis, or real effective thing; becauſe they conceived it contrary to ſcripture. See Copernican *Syſtem*, and Copernicus.

MOCAMBO, in *Geography*, a river of Africa, which runs into the Indian ſea; 15 miles S. of Mozambique.

MOCANERA, in *Botany*, Juſſ. 318, the name by which the *Viſnea Mocanera*, Linn. Suppl. 251, is known in the Canary Iſlands, and which Juſſieu preferred as a generic appellation, becauſe he was informed the perſon from whom the other was derived, was unworthy of botanical commemoration. We have indeed been aſſured of this by the late

Mr. Masson, the discoverer of the shrub, who was very indignant at the name of *Visnea*. Mr. De Visme, designed to be honoured by it, was a merchant at Lisbon, who had a choice garden, and took delight in the cultivation of rare and curious plants, in a country where that taste was then in its infancy. So that, though he might not be a scientific botanist, his claim is equal to that of abundance of persons, on whom a similar honour has been, rather too indiscriminately indeed, bestowed. See VISNEA, or rather, as Schreber more correctly has it, VISMEA.

MOCARA, in *Geography*, a village of Egypt, situated in a chain of mountains, extending across the desert more than 150 miles from E. to W., in the road from Cairo to Siwah, and deriving their name from that of the village; 90 miles W. of Cairo.

MOCARANGA, or MOCARA, which has been erroneously called *Monomatapa*, from the title of the monarch, an extensive country of Africa, situated at some distance from the Indian sea, between 15° and 20' S. lat., and 28° and 36' E. long. But within its whole extent other countries are included, almost as far southward as the Cape of Good Hope, and on the N.W. to the confines of Congo; but on the W. and N.W. it is bounded by Monoemugi. The climate is temperate, though the mountains called Lupata, or the spine of the world, forming a great chain from N. to S., are perpetually covered with snow; the air clear and salubrious, and the soil fertile and well watered, so that its pastures feed a great number of cattle, more valued by the inhabitants than their gold. The country affords plenty of rice, millet, and other grain, but no wheat; fruit trees in abundance, and sugar-canes, which grow without culture; its forests swarm with wild beasts and variety of game; and its rivers abound with fish, and also with gold; nevertheless it is but thinly inhabited. Whilst those lands which are watered by the rivers Cuamo or Zambezi, which encircles the kingdom on the N. and W., and Spiritu Sancto, and others that flow into them, are fertile and productive, the inland parts are sandy, dry, and barren; and the occupiers, who are few in number, are under a necessity of fetching from a great distance water for washing their gold-dust, if their cisterns, for want of rain, fail to supply them. This country, though destitute of horses, and other beasts of burden, is overstocked with elephants, many of which are annually destroyed, so that the Portuguese are plentifully supplied with ivory. The ostriches of this part of Africa are of a large size, and supply grease and oil, which, as the inhabitants conceive, is a sovereign remedy against pains and aches as well as sprains and rigidity of the limbs, when taken inwardly, or applied externally. The natives are black, with woolly hair, they are well formed, robust, and healthy, and more agile and active than those of Quiloa, Mombaso, and Melinda. They are fond of war, which they prefer to traffic; and those of the lower class are habituated to diving; and by this practice, they fetch up from the bottoms of their rivers and lakes the mud that yields gold; and having separated the one from the other, they exchange their gold with the Portuguese for cotton cloths, and other articles of merchandize, which are brought hither from India and Europe. Their food consists of the flesh of oxen and elephants, salted and dried fish, and a variety of fruits; and also of bread made in their cities of rice or millet; and their drink is sour milk and oil of Sesame or Turkey wheat. Persons of superior rank and opulence have strong liquors made of honey, millet, and rice, and also palm-wine, which is held in high estimation. Their dress extends only from the girdle downwards; that of the common people is made of dyed cotton; but persons of quality wear Indian silks, or cotton embroidered with gold, over which they commonly have a lion's skin, or that of some other wild beast, with the tail hanging behind, and trailing on the ground. The men marry as many wives as they can maintain; but the first is the chief, and her children are the father's heirs, the rest being treated as servants. The king, or emperor, is said to have 1000 wives, all of whom are the daughters of some of his vassal princes; but the title and honour of queen belong exclusively to the first. He neither wears in his own dress nor suffers his subjects to wear any clothes that are manufactured out of his own dominions, under an apprehension that they conceal some charm or poison. The metropolis of this empire is called "Benematapa," or "Banamatapa," and by some writers it is called "Medrogan." It is a spacious city, about 20 miles W. of Sofala. The houses are neat, white-washed within and without, and adorned with beautiful cloths of cotton, finely wrought or dyed. But the greatest ornament of the city is the imperial palace, which is a large and spacious edifice of wood, well flanked with towers, with four avenues, or stately gates, at which a numerous guard is constantly stationed. The emperor's guard is said to consist of women lightly armed. The Portuguese have two fortresses, and another station near the mountains of Fura, which are said to abound in gold. One of the emperor's queens is said to be the protectress of the Portuguese, and another of the Moors. The emperor, by the account of a Dutch commodore who visited this country in 1606, ruled from Mozambique to the Cape of Good Hope. The chief province is in an isle or delta, between two branches of the Cuamo and the Espirito. This isle is about 750 French leagues in circuit, and the chief town was Banamataxa. At that period there were many subject kings, and the emperor had a guard of 200 deys. Among the rivers that roll gold are the Panami, Luanga, and Mangiano. But later accounts of this country, and of other Portuguese settlements on the eastern coast of Africa, are wanting; the Portuguese, probably from motives of interest, are silent.

MOCAUMPOUR, capital of a country of the same name to the N. of the country of Bengal; 40 miles S.S.E. of Catmandu. N. lat. 27° 35'. E. long. 85° 37'.

MOCEFU, a town of Peru, in the diocese of Truxillo; 10 miles S.E. of Lambayeque.

MOCENIGO, ANDREW, in *Biography*, a noble Venetian, flourished in the early part of the sixteenth century, and was employed in the public service of his country, which he managed with success. As an author he wrote in Latin a "History of the War sustained by the Republic of Venice, in consequence of the League of Cambray, from 1500 to 1501, in four Books:" and he composed a poem in Latin verse on the war with Bazajet II., which is lost. Moreri.

MOCHA, a small island in the Pacific ocean, near the coast of Chili. S. lat. 38° 30'.

MOCHA, or *Mokha*, a town of Arabia, in the province of Yemen, situated on a dry and barren spot in that part of the province called Tehama, or the plain country. Its fortifications are the walls which surround it, some towers on the way to Musa, dignified with the name of castles, and two other castles of the same sort, upon the two arms of the harbour. The greatest of these two castles is called "Kalla Tejar," and the smallest "Kalla Abdurrah," from the names of two saints buried in these places. These are provided with some few pieces of cannon. The houses in the city are built of stone: some of them are handsome; but others, both within and without the walls, are not better than the common huts that are found through all the

Tehama.

Tehama. In the environs of this city are abundance of date trees and many agreeable gardens. Mocha was built about four centuries ago, and like many other cities of the Tehama, it owes its origin to a ſaint, the celebrated ſcheik Schædeli. This ſaint was in ſuch reputation, that a multitude of perſons from the moſt diſtant countries reſorted hither to receive his inſtructions. His hermitage ſtood on the ſea-ſide, and many huts were built around it for the accommodation of his followers: theſe formed a village, which by degrees was enlarged into a city. Some other circumſtances contributed to give celebrity to its eſtabliſhment. A ſhip bound from India to Jidda caſt anchor, about 400 years ago, in this latitude. Several of the crew, perceiving huts in the deſert, had the curioſity to viſit them. The ſtrangers were hoſpitably received by the ſcheik, and regaled with coffee, to which he aſcribed ſingular virtues. The Indians, who were unacquainted with the uſe of coffee, thought that it might be a ſeaſonable remedy to the maſter of the ſhip, who was ill. Schædeli aſſured them, that he ſhould not only be cured by the efficacy of his prayers and of the coffee, but that if they would land their cargo there, they might diſpoſe of it to conſiderable advantage. Aſſuming at the ſame time the air and the tone of a prophet, he told them that a city ſhould one day be built upon that ſpot, which would become an eminent mart of the Indian trade. The maſter of the veſſel viſited the prophet, drank the coffee, and was reſtored to health. Many Arabs flocked to hear the preaching of the ſaint, and among them were ſeveral merchants, who purchaſed the whole cargo. The Indians returned home, related their adventure, and induced many of their countrymen to reſort to this place. An elegant moſque was raiſed upon the tomb of the prophet, which ſtands without the walls of the city. The well that ſupplies the inhabitants with water, and one of the city gates, bear his name. His deſcendants are held in honour, and enjoy the title of ſcheik; the people ſwear by him; and his name will be remembered as long as Mokha ſtands. He is not only the patron of Mokha; but all the Muſſulmans who drink coffee mention him every morning in their prayers, eſteeming him as *their* patron; thanking God that through his mediation mankind were taught the uſe of coffee, and imploring the favour of heaven on the ſcheiks, his deſcendants. Mokha was the laſt city in Yemen of which the Turks retained poſſeſſion. It is ſaid that the Arabs did not conquer but buy it. Since the Turks were diſpoſſeſſed, it has never had another maſter but the Imam. A Dola, having enriched himſelf in the government of this city, fortified it, and drew a ditch round it, which is now filled up. He was ſuſpected of aſpiring to independence, and was caſt into priſon. From that time, a Dola has never been continued above three years in this lucrative poſt. After the monſoon ſeaſon, the Dola of Mokha is annually obliged to give an account of his adminiſtration, and is either confirmed in his employment, or inſtantly recalled to Sana. Many Jews live here in a ſeparate village, as in the other cities of Yemen. Here are alſo about 700 Banians, Rajaputs, and other Indians, ſome of whom are merchants, and others gain a ſubſiſtence by the exerciſe of different mechanic arts. When they have made a ſmall fortune, they return home to India; and on this account are always regarded as ſtrangers. Several nations frequently traded to this port. The Portugueſe, who two centuries ago were very powerful on the Arabic gulf, have long ſince ceaſed to ſend ſhips thither. The Dutch rarely appear here; and the French never in time of war, though they ſtill continue to rent warehouſes. The Engliſh at preſent engroſs, by way of India, almoſt excluſively, the whole trade of this place, which is conducted for them by a Banian. The trade of Mokha being ſo conſiderable, the cuſtoms muſt afford a large revenue to the Imam. The Turks, Arabs, and Indians, pay eight or ten *per cent.* upon their value; after they have been inſpected at the cuſtom-houſe: all Europeans enjoy the privilege of having their goods inſpected in their own warehouſes, and of paying only three *per cent.* upon their value. The Indians of late, ſince the Engliſh have become ſo powerful in Bengal, pay only three *per cent.* but the merchants in Mokha pay likewiſe five *per cent.* on all Indian goods which they purchaſe. There is alſo a tonnage duty, regulated not by the tonnage of the veſſel but by the number of its maſts. A merchant, however, who lades a large European ſhip with coffee in this port, receives from the Dola a premium of 400 crowns. The Arabs have ſcarcely any article for exportation except coffee, and of this the Indians are not very fond. The Engliſh ſhips muſt return empty to India, if they did not gain conſiderably by carrying money, with which the Arabian merchants entruſt them. When a foreign veſſel arrives in the road of Mokha, it muſt not ſalute with guns, but only hoiſt a flag. It is obſervable, that the trade on the coaſts of the Red ſea cannot be advantageous to any nation which have not ſettlements in India. The Arabians make no uſe of the productions of Europe. There is, indeed, a quantity of iron ſold in Arabia, which has in times paſt been purchaſed chiefly from the Danes. A ſtranger cannot be too much on his guard againſt Mahometan brokers. He will find it advantageous to addreſs himſelf rather to the Banians, among whom are many conſiderable merchants, who are very honeſt men. N. lat. 13° 19′. E. long. 43° 23′.

Mr. Bruce, in his "Travels to diſcover the Source of the Nile," mentions two other Mochas, beſides that which we have above deſcribed. The firſt is in Arabia Deſerta, in N. lat. 30° nearly, not far from the bottom of the gulf of Suez. The ſecond is in S. lat. 3°, near Terſhiſh on the coaſt of Melinda. The meaning of Mocha, he ſays, is in the Ethiopic *priſon*, and it is particularly given to thoſe three places, becauſe in any of them a ſhip is forced to ſtay or be detained for months, until the change of the monſoon ſets her at liberty to purſue her voyage.

MOCHICAGUI, a town of New-Mexico, in the province of Cinaloa; 60 miles W.N.W. of Cinaloa.

MOCHLIA, from μοχλος, *a lever*, in *Surgery*, a reduction of bones from an unnatural to a natural poſition.

MOCHO, or MOCOA *Stones*. See AGATE and DENDRITIS.

MOCHOW, in *Geography*, a town of Bohemia, in the circle of Kaurzim; 12 miles W.N.W. of Kaurzim.

MOCK-BIRD, *Indian*, in *Ornithology*. See TURDUS *Cyanus*.

MOCK-*Bird of Guiana*. See ORIOLUS *Americanus*.

MOCK *Lead*, in *Mineralogy*, a name given by the Engliſh writers to a ſort of foſſil, called alſo *blende* and *galena*.

MOCK *Nightingale*, in *Ornithology*. See MOTACILLA *Atricapilla*.

MOCK *Orange*, in *Botany*. See PHILADELPHUS.

MOCK *Privet*. See *Mock* PRIVET.

MOCK, or running a *muck*, is a practice that has prevailed time immemorial in Batavia. To *run a muck*, in the original ſenſe of the word, is to get intoxicated with opium, and then ruſh into the ſtreet, with a drawn weapon, and kill any one that comes in the way, till the party is himſelf either killed or taken priſoner. If the officer takes one of theſe *omocks* or *mohawks* (as they have been called by an eaſy corruption) alive, he has a conſiderable reward, and the unhappy wretches are always broken alive on the wheel: but ſuch is the fury of their deſperation, that three out of four are

are neceſſarily deſtroyed, in attempting to ſecure them. See Amok.

MOCKELN, in *Geography*, a lake of Sweden, in the province of Smaland; 25 miles S.W. of Wexio.

MOCKERN, a town of the duchy of Magdeburg; 16 miles E. of Magdeburg.

MOCKJACK Bay, a bay of America, on the coaſt of Virginia, in the Cheſapeak. N. lat. 37° 24′. W. long. 76° 23′

MOCLIN, a town of Spain, in the province of Granada; 12 miles S. of Loja.

MOCO, in *Commerce*, a ſmall ſilver coin in the Weſt Indies, which in ſome places is $\frac{1}{4}$th of the dollar, and in others $\frac{1}{8}$th.

MOCOA, in *Geography*, a town of South America, in the province of Popayan; 70 miles S.E. of Popayan.—Alſo, a town of Mexico, in the province of Culiacan, on the river St. Sebaſtian; 90 miles N.W. of Culiacan.

MOCOCO, or Maucaco, in *Zoology*. See Lemur *Catto*.

MOCODAME, in *Geography*, a ſmall iſland near the S.E. coaſt of Nova Scotia. N. lat. 45° 4′. W. long. 61° 20′.—Alſo, a river of Sumatra.

MOCOES, a tribe of the Eboe ſlaves, brought from the interior of Africa. See Eboes.

MOCO-MOCO, a town of Sumatra, the capital of Anac-Soongey, on the S.W. coaſt. This country roſe from the ruins of Indrapour, and extends on the ſea-coaſt from Mandoota river to that of Oori. A ſmall tax was laid on the people of Anac-Soongey, in ſatisfaction for the murder of a prince by the raja of Indrapour, which is now paid to the ſultan of Moco-Moco. The tax is a ſoocoo (the 4th part of a dollar), a bamboo of rice, and a fowl, from each village annually. The government of Anac-Soongey is Malay, but a great part of the country dependent upon it is inhabited by the original dooſoon or village people. The chiefs are obliged to attend the ſultan, and carry their contribution or tax; but his authority is very much limited. The officers next in rank to the ſultan are called Mantrié, a corruption, as ſome have ſuppoſed, of Mandarin; 30 miles S.W. of Indrapour. S. lat. 2° 25′. E. long. 101° 12′. Marſden's Sumatra.

Moco-Moco, or *Little Oroonoko*, a river of South America, which runs into the Atlantic, a little S. of Oroonoko.

MOCORITO, a town of Mexico, in the province of Culiacan; 72 miles N.W. of Culiacan.

MOCOS, a collection of ſmall iſlands in the Indian ſea, near the coaſt of Siam. N. lat. 13° 50′. E. long. 97° 52′.

MODAGHIRY, a town of Hindooſtan, in Myſore; 13 miles N. of Vencatighery.

MODAIN, Madain, or *el Modain*, a town of the Arabian Irak, on the ſide of the Tigris, on the ſcite of the ancient Cteſiphon. It is ſaid by Herbelot to have been founded by Sapor and enlarged by Choſroes, who built a palace here that was the moſt magnificent in all the Eaſt. In 637 this place was taken and plundered by Said, the lieutenant of Omar. The riches of which it was deſpoiled were immenſe, conſiſting, in part, of the throne, the crown, the royal ſtandard, and carpet of the ancient Perſian kings; 20 miles S. of Bagdad.

MODAL, in *Logic*, &c. a term applied to propoſitions which include certain conditions and reſtrictions.

Modal, in *Muſic*. The characters for time in the firſt ſtages of figurative muſic or counter-point were called *modal ſigns* for the moods.

The different modes or moods for aſcertaining the *quantum* of each tact, or pulſation of time in muſic, were the following:

○ ○3, for a perfect long, or three breves.

○, a perfect breve, or three ſemibreves.

☉, two imperfect breves, and, in the compoſitions of Tallis and Bird, ſometimes three minims.

C, an imperfect breve, or two ſemibreves.

Beſides theſe, there were others for a ſpecies of jig time, in which ſemibreves or minims were ternary, and moving in triplets, while the longer notes were binary: C 3, C 2, C3, &c. Zacconi, Prat. Muſ. lib. ii. cap. 54. makes the modal ſigns amount to fourteen.

MODANE, in *Geography*, a town of France, in the department of Mont Blanc, and chief place of a canton, in the diſtrict of St. Jean de Maurienne; 15 miles E. of it. The place contains 925, and the canton 3267 inhabitants, on a territory of 450 kiliometres, in 7 communes.

MODBURY, a market-town and borough, ſituated in the hundred of Ermington, and county of Devon, England. The town conſiſts chiefly of four ſtreets, running in the direction of the cardinal points, and croſſing each other at right angles. It is a borough by preſcription, but has loſt its right of ſending members to parliament, having petitioned to be exempted from that *burthen*, as it was then conſidered, in the reign of Edward I. The plea of exemption was the poverty of the inhabitants, who were unable to pay their repreſentatives, as was cuſtomary at that early period. Modbury is now governed by a portreeve (uſually ſtyled mayor), two conſtables, and ſeveral other officers, who are elected annually at a court-leet held at Michaelmas. All perſons who poſſeſs any freehold within the borough are liable to be choſen; being conſidered in the light of freemen or free burgeſſes. Even ſo late as the commencement of the laſt century, it appears from the records, that the borough-court here took cognizance of all debts under forty ſhillings; and in the reign of Charles I. the ſame records ſhew that the inhabitants poſſeſſed the authority of enrolling deeds in the rolls of the borough. The chief ſupport of this town is its woollen trade, which was formerly much more conſiderable than at preſent. A great quantity of yarn was likewiſe ſpun here and in the neighbourhood about fifty years ago, at which time a weekly market was held, diſtinctly to facilitate the ſale of that article. This market has long been diſcontinued, but to preſerve the right, the bell ſtill rings for the yarn-market at twelve o'clock. A pluſh and hat manufactory have alſo been eſtabliſhed of late years. The petty ſeſſions for the hundred are held here. Thurſday is the market-day for proviſions.

The population of this town, according to the parliamentary returns of 1801, compriſed 1813 perſons, 832 males, and 981 females, of which number 862 were returned as engaged in trade, and 944 in agriculture.

The church of Modbury is a very ſpacious and handſome building, ſurmounted by a lofty ſpire, of later erection than the reſt of the edifice. On the ſouth aiſle ſtands a fine alabaſter ſtatue, in armour, ſuppoſed to be the effigy of one of the Champernoune family. Beſides the eſtabliſhed church, there are two other buildings in this town appropriated to divine worſhip; one belonging to the Preſbyterians, and the other to the Anabaptiſts. Here was formerly an alien priory, dependent on the abbey of St. Peter ſur Dive, in Normandy, which ſeems to have been founded ſhortly after the conqueſt. Its religious inmates were monks of the order of St. Benedict. On the diſſolution of the alien monaſteries, in the reign of Henry VI., this priory was granted to the college at Eaton. The preciſe ſcite on which it ſtood is uncertain, but as there are two fields adjoining to the weſtern ſide of of the church-yard, ftill called "Priors'-parks," it was moft probably fituated fomewhere near that fpot. Indeed, on the oppofite fide of the road which paffes thefe parks, there appear fome remains of an ancient building, which may have formed part of the priory.

The proprictor of the manor here, at a very remote period, was fir James Okeftone, or Oxton, from whofe family it paffed into that of the Champernounes, who poffeffed a fplendid manfion immediately adjoining to the town, only a fmall portion of which is now ftanding. Of the grandeur of this feat, and the magnificent manner in which its owner lived, tradition fpeaks very highly. They are faid, in particular, to have kept a fine band of fingers and muficians, with whofe execution queen Elizabeth was fo much delighted, that fhe requefted the loan of them for a month, but being refufed by Mr. Champernoune, out of pique found fome pretence to fue him at law, and occafion his ruin; he being compelled to fell no lefs than nineteen manors to fupport the litigation.

The vicinity of this town is adorned with a number of family feats, fome of ancient and others of modern erection. Wimpfton, the ancient manfion of the Fortefcues, is particularly remarkable as being the houfe in which the celebrated fir John Fortefcue was born. This gentleman raifed himfelf by his talents to the dignity of chief juftice and chancellor in the reign of king Henry VI., and wrote a work entitled "De Laudibus Legum Angliæ," which is ftill held in great repute among legal antiquaries. The other feats of note near Modbury, are Train, Fleet-houfe, Madridge, Fowlefcombe, Stowford, Butterford, Shilfton, and Fardel, which laft was long in poffeffion of the Raleighs. Polwhele's Hiftory, &c. of Devonfhire, two vols. folio. Beauties of England and Wales, vol. iv.

MODDAPOUR, a town of Bengal, on the right bank of the Ganges; 27 miles N. of Mahmudpour.

MODDIGONG, a town of Hindooftan, in Goondwana; 10 miles N. of Ramteak.

MODDIGUBA, a town of Hindooftan, in the circar of Gooty; 10 miles W. of Amantpour.

MODE, or Mood, *Modus*, in *Philofophy*, a manner of being; or a quality or attribute of a fubftance, or fubject, which we conceive as neceffarily depending on the fubject, and incapable of fubfifting without it.

Mr. Locke defines modes to be thofe ideas (he fhould have faid *things*) which do not imply any fuppofition of fubfifting by themfelves, but are confidered as mere dependencies, and affections of fubftances.

Our ideas of things may be reduced to two kinds: the one of things, which we conceive feparately, and by themfelves, called *fubftances;* and the other of things which we conceive as exifting in others, in fuch manner as that we cannot allow them exifting without them, and thefe we call *modes* or *accidents*.

It is the characteriftic, then, of a true mode, to have fuch a relation to fome fubject, as not to be clearly and diftinctly conceivable without conceiving the fubject, of which it is a mode, at the fame time: when, on the other hand, the conception of the fubject does not at all infer or require that of the mode.

Thus, what gives us to know that thought is not a mode of extended fubftance, or matter, is, that extenfion, and the other properties of matter, may be feparated from thought, without ceafing to conceive thought all the while.

We always confider things as clothed with certain modes, except we reflect on them in the abftract, or general; and it is the variety of modes, and the relations, that occafions the great variety of denominations of the fame thing. They are the various modes of matter, *e. g.* that make all the diverfity of bodies, or corporeal beings, in nature.

There are various divifions and kinds of modes: as, 1, *effential*, or *accidental*. An *effential* mode, or *attribute*, is that which belongs to the very nature or effence of the fubject in which it is; and the fubject can never have the fame nature without it, as roundnefs in a bowl, folidity in matter, thinking in a fpirit, &c. and this is *primary*, when it is the firft or chief thing that conftitutes any being in its particular effence or nature, and makes it to be that which it is, and diftinguifhes it from all other beings, as roundnefs in a bowl: or *fecondary*, which is any other attribute of a thing, that is not of primary confideration, called a *property;* as volubility in a bowl. An *accidental* mode, or *accident*, is fuch a mode as is not neceffary to the being of a thing; for the fubject may be without it, and yet remain of the fame nature which it had before; or it is that mode, which may be feparated from its fubject, as blacknefs or whitenefs in a bowl, learning in a man, &c.

2. Modes are *abfolute* and *relative*. An *abfolute* mode is that which belongs to its fubject; without refpect to any other beings whatfoever. A *relative* mode is derived from the regard which one being has to others: thus, roundnefs and fmoothnefs are the *abfolute* modes of a bowl; but greatnefs and fmallnefs are *relative*. See Relation.

3. Modes are *intrinfical*, or *extrinfical*. The former are conceived to be in the fubject or fubftance; as when we fay a globe is round, &c. The latter mode is a manner of being which fome fubftances attain by reafon of fomething that is external or foreign to the fubject, and is called external denomination; as the globe lies within two yards of the wall, &c.

4. Modes are alfo *inherent*, or *adherent*; i. e. *proper* or *improper*. *Adherent* modes arife from the joining of fome accidental fubftance to the chief fubject; which yet may be feparated from it; as when a bowl is wet, &c. *Inherent* modes have a fort of in-being in the fubftance itfelf; as the bowl is fwift or round, &c.

5. *Action* and *paffion*, ufing the terms in a philofophical fenfe, are modes which belong to fubftances; as when a fmith with a hammer ftrikes a piece of iron, the fmith and hammer are agents or fubjects of action, and the iron is the patient, or fubject of paffion.

6. Modes may be divided into *natural*, *civil*, *moral*, and *fupernatural*, all which pertain to the apoftle Paul, who was a little man, a Roman by the privilege of his birth, a man of virtue or honefty, and an infpired apoftle.

7. Modes belong either to *body*, or to *fpirit*, or to both. Modes of *body* belong only to matter, or corporeal beings; fuch are *figure*, *reft*, *motion*, &c. Thefe are *primary*, when they belong to bodies confidered in themfelves, whether there were any man to take notice of them or no, as fhape, fize, &c.; or *fecondary*, which are fuch ideas as we afcribe to bodies, on account of the various impreffions that are made on the fenfes of men by them, called fecondary qualities: fuch are all colours, founds, taftes, fmells, and all tactile qualities. (See Quality.) Modes of *fpirit* belong only to minds, fuch are *knowledge*, *will*, &c. Modes belonging to body and fpirit, are called mixt or human modes, becaufe they are found in human nature; fuch are *fenfation*, *imagination*, *paffion*, &c. in which there is a concurrence of the operation of animal and intellectual nature.

8. There are alfo modes of other modes, which, though they fubfift in and by the fubftance, as the original fubject of them, are properly and directly attributed to fome mode of that fubftance; thus fwiftnefs and flownefs are modes of motion, which is itfelf the mode of a body.—Watt's Logic, p. i. c. 2. § 3 and 4.

Mr.

Mr. Locke divides modes into *simple*, and *mixt* or *compound*.

Modes, *Simple*, are combinations of simple ideas of the same kind, or even of the same simple ideas divers times repeated; as a dozen, a score, &c. which are only the ideas of so many distinct units put together.

The modifications of any simple idea, Mr. Locke observes, are as perfectly different and distinct ideas in the mind, as those the most remote and inconsistent: thus, *two* is as distinct from *three* as blindness is from heat. With this view that author examines the *simple* modes of space; which are found to be distance, capacity, extension, figure, place, and duration.

The mind has several distinct ideas of *sliding*, *rolling*, *walking*, *creeping*, &c. which are all but the different modifications of motion. *Swift* and *slow* are two different ideas of motion, the measures of which are made out of the distance of time and space put together.

The like variety we have in sounds; every articulate word is a different modification of sound, as are all notes of different length put together, which makes that complex idea called *time*.

The modes of colours might be also very various; some of which we take notice of as the different degrees, or as they are termed *shades of the same colour*. But since we seldom make assemblages of colours without taking in figure also, as in painting, &c. those which are taken notice of, do most commonly belong to mixed modes; as, *beauty*, *rainbow*, &c. All compounded tastes and smells are also modes made up of the simple ideas of those senses.

As to the modes *of thinking*; when the mind turns its view inward upon itself, *thinking* is the first idea that occurs, in which it observes a great variety of modifications; and therefore frames to itself distinct ideas.

Thus the perception annexed to any impression on the body made by an external object, is called *sensation*. Where an idea recurs without the presence of the object, it is called *remembrance*. When sought after by the mind, and brought again in view, it is called *recollection*. When held there long under attentive consideration, it is called *contemplation*. When ideas float in the mind without regard or reflection, it is called in French a *reverie*. When the ideas are taken notice of, and, as it were, registered in the memory, it is *attention*. When the mind fixes its view on any one idea, and considers it on all sides, it is *intention* and *study*.

Of these various modes of thinking, the mind forms as distinct ideas, as it does of white and red, or of a square or a circle.

Modes, *Mixt*, are combinations of simple ideas of several kinds; as in *beauty*, which consists in a certain composition of colour, figure, &c.; *theft*, which is the concealed change of possession of any thing, without consent of the proprietor, &c.

There are three ways by which we get ideas of *mixt* modes: 1. By experience and observation of things themselves: thus, by seeing two men wrestle, we get the idea of wrestling. 2. By invention, or voluntary putting together of several simple ideas of our own minds: so he that first invented printing, had an idea of it first in his mind before it ever existed. 3. By explaining the names of actions we never saw, or notions we cannot see; and by enumerating all those ideas, which go to the making them up: thus, the *mixt* mode which the word *lye* stands for is made up of the simple ideas. 1. Articulate sounds. 2. Certain ideas in the mind of the speaker. 3. Words, the signs of these ideas. And, 4. Those signs put together by affirmation, or negation, otherwise than the ideas they stand for are in the mind of the speaker.

Mixt modes have their unity from an act of the mind, combining those several simple ideas together, and considering them as one complex one: the mark of this union is one name given to that combination.

This gives the reason, why there are words in every language, which cannot be rendered by any one single word of another. For the fashions and customs of one nation make several combinations of ideas familiar in one, which another had never any occasion to make. Such were ὀστρακισμὸς among the Greeks, and *proscriptio* among the Romans.

This also occasions the constant change of languages; because the change of custom and opinion brings with it new combinations of ideas, which, to avoid long descriptions, have new names annexed to them, and so they become new species of *mixed* modes.

Of all our simple ideas, those which have had most *mixed* modes made out of them, are thinking, and motion (which comprehend in them all action), and power, from whence these actions are conceived to flow.

Of this kind are the modes of actions, distinguished by their causes, means, objects, ends, instruments, time, place, and other circumstances; as also of the powers fitted for those actions. Thus *boldness* is the power to do or speak what we intend, without fear or disorder; and this power of doing any thing when it had been acquired by frequent doing the same thing, is that idea we call *habit*; and when forward and ready, upon every occasion, to break into action, we call it *disposition*: thus *testiness* is a disposition or aptness to be angry. Power being the source of all action, the substances, in which those powers are, when they exert this power, are called *causes*: and the substances thereupon produced, or the simple ideas introduced into any subject, are called *effects*. The efficacy by which the new substance or idea is produced, is called in the subject exerting that power, *action*; and, in the subject in which any simple idea is changed, or produced, *passion*: which efficacy, in intellectual agents, we can conceive to be nothing else but modes of thinking and willing: in corporeal agents nothing else but modifications of motion.

Mode, *Division of a*. See Division.

Mode, in *Grammar*. See Mood.

Mode, in *Logic*. See Mood.

Mode is also used for the modification of a proposition; or that which renders it *modal* and *conditional*.

Mode, *Indirect*. See Indirect.

Mode, Fr. a key in *Music*. In plain-chant the modes are numbered.

The ecclesiastical modes are called *authentic*, when the 5th is above the principal, as $\overset{a}{\underset{A}{E}}$; and *plagal*, when the 4th is above the principal, and the 5th below its octave, as $\overset{d}{\underset{D}{G}}$. See Canto-fermo, and Tones *of the* Church.

Modes *of the Ancient Greek Music*. The ancients differ extremely among themselves in defining their modes; obscure in all parts of their music, upon this subject they are nearly unintelligible. They all agree that a mode is a certain system or constitution of sounds, and it seems as if this constitution was in itself nothing more than an octave filled with all the intermediate sounds according to the genus.

In high antiquity, the Greeks had but three modes, at the distance of a tone from each other, which was national:

 the

the lowest being called the *Dorian*, the middle the *Phrygian*, and the highest the *Lydian*.

Afterwards, in dividing the tones into semitones, two other modes were obtained, as the *Ionian* and the *Æolian*; the first being inserted between the Dorian and the Phrygian, the second between the Phrygian and the Lydian.

In process of time the system being extended above and below, musicians established new modes at both extremities, which took their denomination from the first five, adding the prepositions *hyper*, above, and *hypo*, below. Thus the Lydian mode was followed by the hyper-Dorian, the hyper-Ionian, the hyper-Phrygian, the hyper-Æolian, and the hyper-Lydian, ascending: and after the Dorian mode, came the hypo-Lydian, the hypo-Æolian, the hypo-Phrygian, the hypo-Ionian, and the hypo-Dorian, in ascending. These fifteen modes are all enumerated in Alypius. See the plate, where their order and intervals are expressed in Greek characters, and by equivalent notes in the Guido scale. But it must be remembered, says Rousseau, that the hypo-Dorian was the only mode which was used to its whole extent. In proportion as the others mounted, the upper notes were avoided, in order not to exceed the natural compass of the voice. These observations are necessary for the clearing up some passages in ancient authors, which seem to imply that the lowest modes had the highest notes, which indeed was true, in having in their melodies more notes above the key-note. For want of this knowledge, Doni is extremely embarrassed by these apparent contradictions.

Greek theorists differ in the number of modes: while with some they amount to 15, Aristoxenus, according to Euclid, admitted only 13, suppressing the two highest; the hyper-Æolian, and hyper-Lydian. But in the work of Aristoxenus that is come down to us, he only specifies six, concerning which he relates the different sentiments of the times.

At length, Ptolemy reduced the number of these modes to seven; saying that modes were introduced in music in order to vary the melodies by the contrast of grave and acute; for it is evident that they may be multiplied far beyond 15; but these seven suffice to facilitate the transition from one mode to another, by consonant intervals easy to produce.

He therefore includes all the modes in the compass of an octave, of which the Dorian mode was the centre; so that the mixo-Lydian was a 4th above, and the hypo-Dorian a 4th below. The Phrygian a 5th above the hypo-Dorian; the hypo-Phrygian, a 4th below the Phrygian: whence it appears, that to count from the hypo-Dorian, which is the lowest mode, there was the distance of a tone to the hypo-Phrygian; from the hypo-Phrygian to the hypo-Lydian, another tone; from the hypo-Lydian to the Dorian, a semitone; from that to the Phrygian, a tone; from the Phrygian to the Lydian still a tone, and from the Lydian to the mixo-Lydian, a semitone, which extend to a seventh, in the following order:

1	-	F	-	-	Mixo-Lydian.
2	-	E	-	-	Lydian.
3	-	D	-	-	Phrygian.
4	-	C	-	-	Dorian.
5	-	B	-	-	Hypo-Lydian.
6	-	A	-	-	Hypo-Phrygian.
7	-	G	-	-	Hypo-Dorian.

Ptolemy retrenched all the other modes, pretending that these seven occupied all the sounds of the diatonic octave. From these seven modes of Ptolemy, with the addition of the hypo-mixo-Lydian, it is supposed that Guido formed the eight ecclesiastical modes. See TONES *of the* CHURCH.

Such is the clearest notion which we are able to form of the tones or modes of the ancient music; while we consider them as differing from each other only by grave and acute: but still other differences subsisted, which characterized them more particularly: as expression, the kind of poetry to which they were applied, the kind of instrument by which they were accompanied, the rhythm or cadence of the verse, names or airs peculiar to certain people from whom the principal modes had their names: as the Dorian, Phrygian, Lydian, Ionian, Æolian.

There were still other modes, which should rather be called styles or kinds of composition: as the tragic mode, appropriated to the theatre; the nomic, consecrated to Apollo; the dithyrambic, to Bacchus, &c. See STYLE and MELOPŒIA.

In our old music, the word *mode*, or *mood*, was applied to measure or time, in order to fix the relative value of all the notes in a movement by a general sign, which was placed after the clef, at first by circles and semi-circles pointed, or without points, according to the numbers 2 and 3, differently combined. It is from these ancient expedients that we still retain  for common time, and a barred  for a quicker dual measure. See MODAL and PROLATION.

These characters, except the two last mentioned, have long been disused; yet it is necessary to understand them, in order to be able to decipher old music.

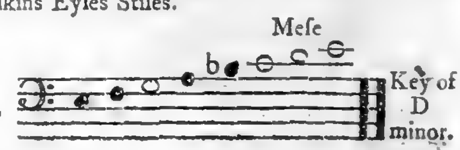
Thus far the chief of this article is from Rousseau, which includes almost all the knowledge on the subject, that the most laborious and profound commentators of the seven ancient Greek writers on music, published by Meibomius, ever conjectured, we dare not say discovered, on the subject.

The general opinion concerning the modes of Ptolemy, till about the middle of the last century, was such as we have described, till sir Fr. Haskins Eyles Stiles formed an ingenious hypothesis concerning them, which was read to the Royal Society in 1759, and afterwards published in the Philosophical Transactions, vol. li. part ii. for 1760, under this title: "An Explanation of the Modes or Tones in the Ancient Grecian Music." Sir Francis in this dissertation endeavours to prove, that the ancients had a double doctrine of the modes, an *harmonic* and a *musical* doctrine By the harmonic doctrine, the modes were all one and the same series of intervals, such as the general system furnishes, only at different pitches; by the musical, they consisted of so many different arrangements of intervals, or species of octave. Sir Francis regarded the harmonic doctrine as only a tuning trick, to produce more readily the different species of octave between the fixed sounds.

He explains this in a diagram, taking his pitch, according to Ptolemy, at hypate meson, our E in the base, and makes all his mutations between that sound and its octave, nete die zeugmenon. And this, according to sir F. E. Stiles, is the diapason chosen by Ptolemy, cap. 2, lib. ii. for the purpose of exhibiting his divisions of the several species.

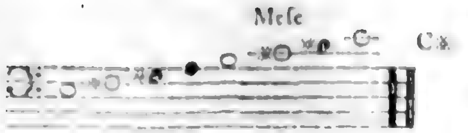
Diagram of the Species of Diapason in the seven Modes admitted by Ptolemy, according to the Doctrine of Sir Francis Haskins Eyles Stiles.

Mixolydian.



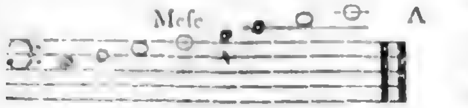
Lydian.

Lydian.

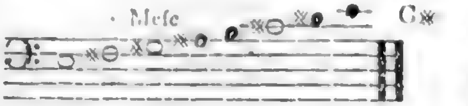


Phrygian.

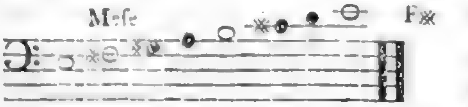
Dorian.



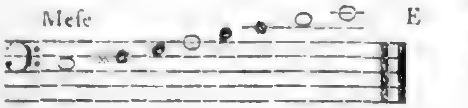
Hypolydian.



Hypophrygian.



Hypodorian.



Sir Francis gives quotations from the ancient Greek writers in confirmation of his doctrine, several of which indeed seem favourable to it; at least they imply a difference on some occasions from the intervals in the natural or great system: this difference he imagines to be expressed by the term μεταβολη, *mutation*.

He very truly asserts, that no transposition of the same melody into a higher or lower key, can have so powerful an effect as a change in the modulation, or succession of intervals; and observes, that modern music has but two considerable changes in the same key; these are from major to minor, and from minor to major. The first seems reserved for pathetic effects.

Sir Fr. Haskins Eyles Stiles falls foul on all his predecessors. After his opinion, we have that of Rousseau, the chief part of whose article in his Dict. de Mus. we have translated, and given whatever is most new and useful in former and subsequent articles, and his opinion on the ancient Greek modes and other articles peculiar to the music of the ancients.

Metastasio, in two letters to Saverio Mattei on the Grecian music, has considered it with his usual elegance, candour, and clearness; but he does not treat of the modes in particular, so much as on ancient Greek music in general. We shall therefore reserve our extracts from these two letters, till Greek music and music of the ancients are considered at large. See SYSTEM.

MODECCA, in *Botany*, a genus of the Cucurbitaceous order, figured in Rheede Hort. Malab. v. 8. t. 20—23, and indicated by Jussieu under *Passiflora*, Juss. Gen. 398. A species of the same, from Sierra Leone, flowered many years ago, in lady Amelia Hume's stove, and still exists there. We believe it to be a perfectly well defined genus, and have proposed to call it *Blepharanthes*, on account of the fringed petals, which make its essential character, and to preserve an analogy with its near ally *Trichosanthes*. We have only waited for a more correct knowledge of the several species, and of some circumstances in the generic character. It is abundantly distinct from *Passiflora*. S.

MODEL, an original, or pattern, proposed for any one to copy or imitate.

St. Paul's church is said to be built after the model of St. Peter's at Rome.

MODEL is particularly used in building for an artificial pattern, made of wood, stone, plaster, or other matter, with all its parts and proportions; in order for the better conducting and executing some great work, and to give an idea of the effect it will have in large.

In all great buildings it is much the surest way to make a model in relievo; and not to trust to a bare design, or draught. There are also models for the building of ships, &c. and for extraordinary stair-cases, &c.

MODEL, in *Painting* and *Sculpture*, is any thing proposed to be imitated. And

Hence, in the academies, they give the term model to a naked man, disposed in several postures, to give an opportunity to the scholars to design him in various views and attitudes.

The sculptors have little models of clay or wax to assist them in their designs of others that are larger, in marble, &c. and to judge of the attitude and correctness of a figure.

Statuaries likewise give the name model to certain figures of clay or wax, which are but just fashioned, to serve by way of guide for the making of larger, whether of marble or other matter.

MODENA, *Duchy of*, in *Geography*, a principality of Italy, bounded on the N. by the duchy of Mantua, on the E. by the Bolognese, on the S. by the republic of Lucca, and on the W. by the duchy of Parma, and part of Tuscany; about 60 miles in its greatest length, and from 20 to 36 in breadth. The soil resembles that of the duchy of Parma; the agriculture is little superior, the middle-men and metayers impeding industry, though some peasants in the mountains are proprietors of land. The breed of sheep is neglected. The country, however, abounds in corn, excellent wine, and other productions. In some parts is found a kind of alkaline earth, which, being reduced to powder, has been used as an antidote to poisons, fevers, dysenteries, and others disorders. In other parts wells are dug, 40 or 60 feet deep, and on the water a reddish petroleum is seen to float, which abounds most in autumn and spring. These wells are enclosed, and every fortnight oil is skimmed off the surface; and this oil is used for embalming, varnishing, painting, and as an ingredient in some medicinal preparations. Amber is dug out of a soil impregnated with petroleum. This duchy affords a variety of petrifactions. In digging wells near Modena, to a certain depth, a particular stratum is found, on penetrating which the water gushes up as from a subterranean lake or river. About 10 miles S. of the capital there is an aperture in the earth called "La Salza," whence, particularly in spring and autumn, ascend, with a very loud noise, smoke, flame, ashes, and stones, attended with a strong smell of sulphur. Carrara, in the S. of this duchy, affords the celebrated marble used in statuary. The chief rivers are the Crostolo, the Secchia, and the Panaro. This duchy is a remnant of the power of the celebrated family of Este, who also possesses the adjacent country of Ferrara, which was seized by the pope in 1598. The remaining territory contains about 320,000 souls, and the city of Modena 30,000; the revenue being 140,000*l.* Since the French revolution, which has produced such changes in the geography, as well as in the general state of Europe, the whole of this duchy forms a part of Italy, and is now divided into

into the departments of the Croſtolo, the Panaro, and the Apennines.

MODENA, the capital of the above duchy, and now capital of the department of Panaro, the ducal reſidence, and a biſhop's ſee, is an ancient, large, tolerably built, fortified town, with a ſtrong citadel, containing a ducal palace, which is large and ſplendid, and diſtinguiſhed by a well furniſhed picture-gallery, a cathedral, many pariſh churches and convents, and from 25,000 to 30,000 inhabitants. It is ſituated in a fertile plain; and its ſtreets are, in general, large, ſtraight, and ornamented with porticoes and piazzas. The univerſity was for a long time under the direction of eminent profeſſors; and the magnificent college of Charles Boromeo, is an academy for 70 or 80 young noblemen. In a chamber under the cathedral tower is the curioſity ſo much talked of by travellers, called "Secchia rapita," which is nothing more than a well-bucket, with iron hoops, hung up by an iron chain, taken in a war from the inhabitants of Bologna, and preſerved here as a trivial monument of courage and victory. The houſe of Eſte poſſeſſed this city ever ſince the year 1288. On the approach of the French, the duke retired from his dominions, with a large ſum of money, to Venice. Upon an armiſtice, he agreed to pay to the republic 7,500,000 livres in caſh, 2,500,000 livres in proviſions and military ſtores, and to give, beſides, pictures and other douceurs; 30 miles S. of Mantua. N. lat. 44° 38′. E. long. 10° 56′.

MODENORE, a town of Hindooſtan, in the circar of Condapilly; 20 miles N.W. of Maſulipatam.

MODERATA, MISERICORDIA, in *Law*, a writ that lies for him who is amerced in a court-baron or other court, not of record, for any tranſgreſſion beyond the quality or quantity of the offence. It is directed to the lord of the court, or his bailiff, commanding them to take a *moderate amercement* of the party. This writ is founded upon Magna Charta.

If a man be amerced in a court-baron on preſentment by the jury, where he did not any treſpaſs, he ſhall not have this writ, unleſs the amercement be exceſſive and outrageous: and if the ſteward of the court, of his own head, will amerce any tenant or other perſon without cauſe, the party ought not to ſue for this writ of moderata miſericordia if he be diſtrained for that amercement; but he ſhall have action of treſpaſs. (New Nat. Br. 167.) When the amercement which is ſet on a perſon is affeered by his peers, this writ of moderata miſericordia doth not lie; for then it is according to the ſtatute 10 Edw. II.

MODERATION, in *Ethics*, is a virtue conſiſting in the proper government of our appetites, paſſions, and purſuits, with reſpect to honours, riches, and pleaſures; and in this ſenſe it is ſynonimous with *temperance*: it is alſo often uſed to denote *candour*.

MODERATO, Ital. in *Muſic*, implies a time neither quick nor ſlow; much reſembling *andante*, but ſomewhat quicker. See ANDANTE.

MODERATOR, in the *Schools*, the perſon who preſides at a diſpute, or in a public aſſembly.

Such a doctor was the moderator, that is, the preſident, at ſuch a diſputation, in ſuch an aſſembly, &c.

MODERATOR *Ring*, in *Anatomy*, is uſed by Valſalva for that ring which the muſcles of the eye make round the optic nerve, at the bottom of the orbit. He alleges, that the exterior fibres of theſe muſcles which riſe from the nerve, muſt ſhorten it when they contract, and when the interior fibres act they muſt compreſs it; ſo that theſe different fibres of the muſcles affect the nervous fluid here very differently.

Valſalva alſo deſcribes ſuch another ring made round the motory nerves of the eye; but acknowledges, that it is neither ſo remarkable nor diſtinct as the former. Med. Eſſ. Edin. Abr. vol. ii. p. 410.

MODERE', Fr. in *Muſic*. See MODERATO.

MODERN, ſomething new, or of our time. In oppoſition to what is antique, or *ancient*.

Modern authors, according to Naude, are all thoſe who have written ſince Boethius: the modern philoſophy commences with Galileo: and the modern aſtronomy with Copernicus.

MODERN *Medals* are reckoned all thoſe that have been ſtruck within theſe three hundred years. See MEDAL.

MODERN, in *Architecture*, is improperly applied to the preſent, or Italian manner of building; as being according to the rules of the antique. Nor is the term leſs abuſed when attributed to architecture purely Gothic.

Modern architecture, in propriety, is only applicable to that which partakes partly of the antique, retaining ſomewhat of its delicacy and ſolidity; and partly of the Gothic, whence it borrows members and ornaments, without proportion or judgment.

MODERN *Muſic*, *Muſica Moderna*, may be divided into two parts: firſt, *antiquo moderna*, which is generally a ſerious ſort of muſic, conſiſting of many parts; and which has been in uſe from Guido's time to the beginning of the laſt century. Secondly, the *modern*, which has been uſed in the two laſt centuries: it is very different from the *antiquo moderna*, being briſker, lighter, gayer, and more ſprightly.

Tha characteriſtics of the firſt ſtate of counterpoint, or muſic in parts, were *plain ſimple harmony*, conſiſting of common chords, of note againſt note; then *figurative harmony*, or notes of different lengths, conſiſting of different figures or characters moving at the ſame time. After this was found to be poſſible, the more artificial contrivances were cultivated of fugue and canon, but without air or melody, except in fragments of canto-fermo, and tunes of ſuch popular ballads as were ſung in the ſtreets, and upon which moſt of the early maſſes in four parts were conſtructed.

MODERN, or *Moddra*, in *Geography*, a town of Hungary; 14 miles N.N.E. of Preſburg.

MODESTY, in *Ethics*, is ſometimes uſed to denote humility; and ſometimes to expreſs chaſtity or purity of ſentiment and manners. Modeſty was deified by the Romans under the name of "Pudicitia;" and at Rome ſhe had two temples, one dedicated to the chaſtity of the nobles, and the other to that of the populace, and alſo altars on which ſacrifices were offered to her. The origin of the diſtinction between the chaſtity of the Patrician ladies, and that of the Plebeians, is thus related by Livy (l. x. c. 25.) Virginia, of a Patrician family, having married a Plebeian named Volumnius, who was, however, afterwards conſul, her ſiſter, looking upon this match to be unworthy her name, having joined with the other matrons, would no longer ſuffer her to partake in the myſteries of the goddeſs of Chaſtity, but drove her out of the temple. Virginia, ſtung with this affront, got a chapel raiſed in the long ſtreet, the ſame where was the goddeſs's temple from which ſhe was excluded, and ſhe dedicated it to the chaſtity of the Plebeian ladies; where the wives, who were not of the ſenatorian order, convened from that time to offer ſacrifice to that goddeſs. Chaſtity was repreſented under the figure of a woman veiled, or ſeeming to point her right-hand, or her fore-finger, to her face, to ſignify that ſhe has no reaſon to bluſh.

MODI, in *Geography*, a ſmall iſland in the gulf of Engia. N. lat. 37° 27′. E. long. 23° 33′.

MODIANORE, a town of Hindooftan, in Myfore; 45 miles E.N.E. of Bangalore.

MODIBOO, a town of Africa, in the kingdom of Bambarra, delightfully fituated on the banks of the Joliba or Niger, which is here very broad, and enlivened with many fmall and verdant iflands, all of them ftocked with cattle, and crowded with villages; 65 miles N.E. of Sego. N. lat. 14° 38'. W. long. 1° 35'.

MODICA, a town of Sicily, in the valley of Noto; 8 miles W. of Noto. N. lat. 36° 51'. E. long. 14° 43'.

MODIFICATION, in *Philofophy*, that which modifies a thing; that is, gives it this or that manner of being.

Quantity and quality are accidents which modify all bodies.

According to Spinofa's fyftem, all the beings that compofe the univerfe are only fo many different modifications of one and the fame fubftance. And the different arrangement and fituation of their parts make all the difference between them.

MODIFICATIVE, fomething that modifies, or gives a thing a certain manner of being.

Father Buffier eftablifhes a new part of fpeech, which he calls *modificative*. Nouns and verbs, he obferves, are fufceptible of divers circumftances or modifications: in the phrafe, *zeal acts*, we have a noun and verb without any modification; but in that, *zeal without difcretion acts rafhly*, the noun and verb are each attended with a modification or circumftance.

The laft kind of words, which ferve to modify nouns and verbs, fince they have no general name in the common grammars, he choofes to call modificatives: which include what grammarians commonly call *adverb*, *conjunction*, and *prepofition*.

MODILLIONS, in *Architecture*, mutules carved into confoles, placed under the foffit or bottom of the drip of the corona in the Corinthian and Roman orders, for fupporting the larmier and cyma, or appearing to perform the office of fupport.

In Grecian architecture, the Ionic order is without modillions in the cornice, and alfo the Roman examples of the fame order, except the temple of Concord at Rome, which has both dentils and modillions.

A fingular and curious example of a modillion cornice, but contrary to the principles of architecture, is to be found in the interior cornice of the Tower of the Winds at Athens, where the projecting part is much thicker than the interior part, where the ftrefs feems to lie, and, confequently, gives the idea of weaknefs.

A fingular example of modillions is to be found in the frontifpiece of Nero at Rome, where they confift of two plain faces, feparated by a fmall cyma reverfa, and crowned with an ovolo and bead.

Another very extraordinary form of modillions is that placed in the frieze of the fourth order of the Colifeum, cut on the outfide, or projecting part of a cyma reverfe form.

In moft examples of the Corinthian and Roman orders, the cornices have both dentils and modillions; but in our opinion, if the two are ufed together, in good proportion to the other parts, fo as to appear diftinctly at a reafonable diftance, the cornice will be overcharged, both in proportion and weight, to the other principal members of the entablature, or the entablature to the whole order; the one or the other ought, therefore, to be omitted in the fame cornice.

In the general difpofition of modillions, if each one is conceived to be divided into two equal parts by a vertical plane at right angles to the furface of the frieze, one of the modillions is fo difpofed, that its dividing vertical furface will be entirely in a plane paffing through the axis of the column, and in the column next the angle of the building there is generally only one modillion between that through which the plane along the axis paffes, and the angle of the cornice.

The vertical fides of modillions at right angles to the face, are generally finifhed with volutes of different fizes, and turned on different fides of the fame line, the greater being that next to the vertical furface, to which they are attached, and the leffer at the extremity.

The foffits of the modillions, fo conftructed, follow the under line of the volutes, and the connecting undulated line which joins them. The upper part of each volute is on the fame level, and is attached to a moulding of the cyma inverfe form, which returns round it, and this moulding is again attached to the corona, which hangs over the modillion.

In fome of the Roman buildings the modillions are not placed over the axes of the columns, neither upon thofe at the extremes, nor over the axes of the intermediate fhafts. In the Pantheon, the modillion next each angle of the building has its vertical fide, which is oppofed to the next modillion nearer to the central plane of the portico, over the axis of the column, and confequently the whole breadth of the modillion on one fide of the axis entirely, and on that fide next to the angle of the building. In the whole portico are forty-feven modillions, including the one at each extreme; the intervals are, therefore, forty-fix in number, and forty-four between the columns that are between their axes. The portico is octo-ftyle, and, confequently, the inter-columns are feven in number: from this it will be found, that if the columns were placed equidiftantly, the number of inter-modillions would be $6\frac{2}{7}$ths in number. In this temple the correfponding intervals are very irregular. The two extreme ones are, according to Defgodetz, $9' \, 4\frac{1}{2}''$, and $9' \, 2\frac{1}{4}''$: the next two, nearer the centre, are $9' \, 5\frac{1}{4}''$, and $9' \, 1\frac{7}{8}''$: the next two, ftill nearer to the centre, are exactly equal, being $9' \, 5''$ each, and the central intercolumniation is $10' \, 4\frac{3}{4}''$: fo that the modillions appear to be equally divided, without any regard to the axis of the columns. The fame irregularity in the difpofition of the modillions may be obferved in the temple of Concord, and in that of Jupiter the Thunderer. In the three remaining columns of the temple of Jupiter Stator, each column has a modillion placed over its axis, and each inter-column has three modillions regularly difpofed: the diftance between the lower ends of the fhafts are 3 mod. 4 pa. $\frac{1}{2}$, and the columns are in height 20 modules, 6 parts $\frac{5}{7}$ths.

In the Pantheon, the modillions are placed in the pediment, contrary to the authority of Vitruvius.

MODILOWA, in *Geography*, a town of Poland, in Volhynia; 36 miles N.E. of Zytomiers.

MODIN, a village of Paleftine, fituated on a hill, deferving of notice, on account of the tomb of the Maccabees, and alfo of a victory obtained by Judas Maccabæus, over Antiochus Eupator; 14 miles E.S.E. of Jaffa.

MODINAGUR, a town of Hindooftan, in Bahar; 25 miles E.N.E. of Hajipour. N. lat. 25° 34'. E. long. 85° 51'.

MODIOLI, in *Natural Hiftory*, a name given by fome authors to the trochitæ or fingle joints of the rays of the petrified magellanic ftar-fifh, which, when connected in numbers together, form that foffil called entrochus. Others have alfo ufed this word, *modiolus*, to exprefs the compound body, or entrochus itfelf. Though the general form of the trochitæ be thin and flat, yet they are fometimes found confiderably thick; and though the entrochi or compound modioli are ufually fo many cylinders of equal diameter in all parts, yet there are fometimes found fuch as are thick in the middle, and thence gradually taper to each end; fome alfo alſo are compoſed of joints, each of this form; theſe differ very greatly from the common kind, and inſtead of conſiſting of a number of little wheels, are made up of a ſeries of little barrels, joined, as it were, end to end.

MODIOLUS, from *modus*, a meaſure, in *Surgery*, ſince it was formerly ſo conſtructed, that it would only enter to a certain depth: the crown or ſaw of the trepan. Anciently it reſembled in ſhape the nave of a wheel.

MODIUM, in *Geography*, a town of Norway, in the province of Aggerhuus; 20 miles W. of Chriſtiania.

MODIUS, in *Antiquity*, a kind of dry meaſure in uſe among the Romans for ſeveral ſorts of grain.

The modius contained thirty-two heminæ, or ſixteen ſextaries; or $\frac{1}{3}$ of the amphora; amounting to an Engliſh peck. See MEASURE.

MODIUS, FRANCIS, in *Biography*, a learned critic, was born at Oudenburg, in Flanders, in 1546. The wars of the Low Countries obliged him to retire to Cologne, and he ſpent the greater part of his life in Germany. Being at Bonne in 1587, he loſt all his effects, and was himſelf dangerouſly wounded. Towards the cloſe of life, he was preſented with a canonry at Aire, where he died in 1597. Modius wrote annotations upon many of the Latin claſſics, which are moſtly to be found in his "Lectiones Nov-antiquæ," which were firſt printed at Frankfort in 1584, and were reprinted in letters by Gruter, in the fifth volume of his "Theſaurus Criticus." He was author likewiſe of poems and other pieces. Moreri.

MODO & *Forma*, in *Law*, a phraſe uſed in proceſſes and pleadings, by which the defendant abſolutely denies the thing charged on him by the plaintiff, *modo & forma declarata*, in the manner and form ſet forth.

The civilians in the like ſenſe ſay, *negat allegata, prout allegantur, eſſe vera*.

MODON, in *Geography*, a ſea-port town on the S.W. coaſt of the Morea; with a large and ſafe harbour. The town is the reſidence of a pacha, and ſee of a Greek biſhop; 42 miles W.S.W. of Miſitra. N. lat. 36° 58′. E. long. 21° 35′.

MODRITZ, a town of Moravia, in the circle of Brunn; five miles S. of Brunn.

MODRSAW, a town of Auſtrian Poland, in the palatinate of Cracow; 24 miles W. of Cracow.

MODRUSCH, a town of Auſtrian Croatia, the ſee of a biſhop; 24 miles W.N.W. of Sluin.

MODULATION, from *Modulatio*, Lat., in *Muſic*, is one of the moſt important terms of a muſical dictionary. In the articles COMPOSITION and COUNTERPOINT, it has been treated after our own ideas and experience; here we ſhall give our readers the rules laid down by others, not to confute, but to confirm and ſtrengthen our own. And firſt, we ſhould give Padre Martini's inſtructions, and thoſe of Dr. Pepuſch on the ſubject, as the moſt profound contrapuntiſts of Italy and Germany during the early part of the laſt century, if theſe learned theoriſts had not adhered ſo religiouſly to the eccleſiaſtical modulation of the old maſters, founded on the modes or tones of the church, ſo as to preclude all the modulation of ſecular muſic, which has been extended, and in many inſtances improved, during the laſt hundred years. We ſhall, therefore, now chiefly tranſlate and confine ourſelves to the article *Modulation* in the dictionary of Rouſſeau, in which it is amply and clearly treated, according to the practice of the beſt maſters at the time of his writing; that is, 30 or 40 years ago. See works on the ſame ſubject by ſubſequent writers ſtill living, ſuch as Frike, Bemitzrieder, Kollmann, &c.

But firſt we muſt obſerve, that *to modulate* during the ſixteenth century, implied nothing more than a change of voice from one ſound to another; but the ingenious citizen of Geneva, more conſonant to preſent practice in muſic, defines modulation, "the manner of eſtabliſhing and treating a key;" but adds, that the word, at preſent, generally implies the art of conducting melody and harmony, ſucceſſively, into many keys, in a manner agreeable to the ear, and according to rule. If the key is announced by harmony, it is from harmony that the laws of modulation ariſe.

Theſe laws are eaſy to conceive, but difficult rigorouſly to obſerve. To modulate properly in the ſame key, we muſt begin firſt by running through all the notes of that key in good melody, frequently repeating its eſſential chords, and ſtrongly marking them. That is, paſſing from the chord of the 7th to the 5th, or $\frac{6}{5}$ of the 7th to the key-note; but in various ways to avoid monotony. Secondly, to make no cloſes, nor to repoſe but upon thoſe two chords, or at moſt on that of the 4th of the key, called by the French the ſubdominant, or 5th below the key. Thirdly, never to alter any of the ſounds of the principal key by a flat or ſharp, which would lead to another key.

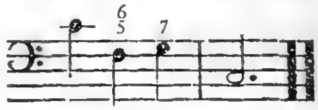
But to paſs from one key to another, which is now underſtood to be the principal buſineſs of modulation, analogy muſt be conſulted, with reſpect to the relation of keys, and the number of chords appertaining to two keys.

Let us begin by a major key, or key with a ſharp 3d. Whether we conſider the 5th of the key as being more immediately related and connected with it of any ſound except the octave of the key-note; or whether we regard it as the firſt ſound that is heard in the reſonance of the key-note, the 5th will always be found the moſt agreeable interval upon which to eſtabliſh a modulation the moſt analogous to that of the key-note.

The 4th of the key, if not a part of the chord of the key-note, the key-note is at leaſt a part of the chord of the 4th. For if C E G form the chord of the key-note, that of the 4th will be F A C; thus C is the bond of union between the two keys. Indeed it is only neceſſary to change one ſound of the principal key to form the ſcale of its 5th above, and 5th below, or 5th and 4th of any major key. In the key of C, an F♯ or a B♭ does the buſineſs.

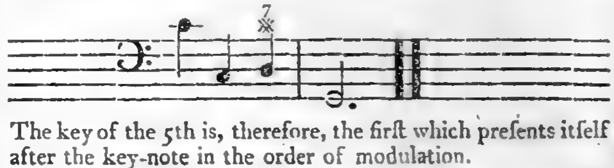
There are two minor chords in the key of C, in which only one note differs from the chord of C, as A *c e*, and *e g* B. But the ſharp 7th, and other accidents which happen to the chords and melody of theſe minor keys, changes their character ſo much, that the double relation between the chords of C and A, and C and E is ſoon effaced.

As all the ſounds of the ſcale of C are compriſed in the chords of the key-note, and its two 5ths,



See plates throughout this article.

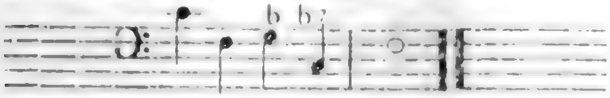
the gammut or ſcale of C, if altered only by one ſingle ſharp, furniſhes the ſcale and chords of G, the 5th above C, which ſhews the great analogy between theſe two keys, and facilitates the means of paſſing from one to the other by one alteration only.



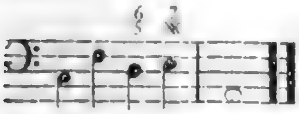
The key of the 5th is, therefore, the firſt which preſents itſelf after the key-note in the order of modulation.

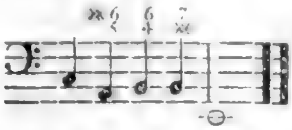
The

The fame fimplicity of relative founds between the key-note and its 5th above is alfo found to fubfift between the key-note and its 5th below, or 4th above.



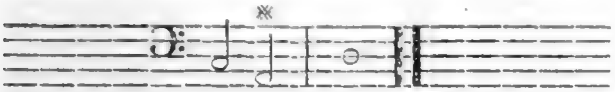
Though the modulating from C to A minor, its 6th, and from C to E minor, its 3d, is only by the change of one note in the chords, the fharp 7th muft be heard in one of the chords of thefe minor keys, to make either A or E a key-note.





Thefe immediate modulations furnifh the means of paffing to more remote keys by the fame rules, and of returning afterwards to the key-note, of which we muft never lofe fight.

We have four regular modulations from the key of C major; E F G A. To modulate into D, wholly unrelative to C, it muft be brought about by means of a confonant movement of the fundamental A with a fharp 3d.



But we muft dwell but an inftant in this modulation, left the key of C is forgotten, which itfelf is altered in going into D. A long period in D would require intermediate modulations to return to C, into which it would be dangerous to wander. No good modulation into B, the fharp 7th of C, can have place, at leaft immediately, as it has no true 5th, and would lead to a harmony too fudden and remote from that of the principal key. In every modulation, all the parts muft change the key at the fame inftant, to avoid carrying on two modulations at the fame time. Huygens, fays Rouffeau, has well remarked, that the prohibition of two fucceffive 5ths has this rule for its principle; for it is impoffible to have many perfect fucceffive 5ths between two parts, without modulating into two unrelative keys. The hexachords are compofed of pure harmony to fundamental bafes, without modulation. The defcending fcale in the *règle de l'octave*, modulates into the 5th of the key. But, in fact, only three notes in the bafe can afcend in one key, diatonically; the 4th note arrives at a new key to the top of the fcale, which produces a perpetual modulation by 4ths, from C natural into all the 23 keys.

To modulate on a keyed inftrument, is ufually done in arpeggio, by preluding extempore, of which the variety, to a man of fcience, is unbounded. Abel, no leffon-player on the clavichord or harpfichord, poffeffed this talent to a wonderful degree.

MODULE, in *Architecture*, a certain meafure taken at pleafure, for regulating the proportions of columns, and the fymmetry or diftribution of the whole building.

Architects ufually choofe the diameter or femidiameter of the bottom of the column for their module; and this they fubdivide into parts or minutes.

Vignola divides his module, which is a femidiameter, into twelve parts, for the Tufcan and Doric; and into eighteen, for the other orders.

The module of Palladio, Scamozzi, M. Cambray, Defgodetz, Le Clerc, &c. which is alfo the femidiameter, is divided into thirty parts, or minutes in all the orders.

Some divide the whole height of the column into 20 parts for the Doric, 22½ for the Ionic, 25 for the Roman, &c. and of one of thefe parts they make a module, by which to regulate the reft of the building.

There are two ways of determining the meafures or proportions of buildings: the firft by a fixed ftandard meafure, which is ufually the diameter of the lower part of the column, called a module, fubdivided into fixty parts, called minutes. In the fecond there are no minutes, nor any certain and ftated divifion of the module; but it is divided occafionally into as many parts as are judged neceffary. Thus the height of the Attic bafe, which is half the module, is divided either into three, to have the height of the plinth; or into four, for that of the greater torus; or into fix, for that of the leffer.

Both thefe manners have been practifed by the ancient as well as the modern architects; but the fecond, which was that chiefly ufed among the ancients, is in the opinion of Perrault preferable.

As Vitruvius, in the Doric order, has leffened his module, which, in the other orders, is the diameter of the lower part of the column, and has reduced that great module to a mean one, which is a femidiameter; M. Perrault reduces the module to a third part for the fame reafon, *viz.* to determine the feveral meafures without a fraction. For in the Doric order, befide that the height of the bafe, as in the other orders, is determined by one of thefe mean modules; the fame module gives likewife the heights of the capital, architrave, triglyphs, and metopes. But our little module, taken from the third of the diameter of the lower part of the column, has ufes much more extenfive; for, by this, the heights of pedeftals, of columns, and entablatures, in all orders, are determined without a fraction.

As then the great module or diameter of the column has fixty minutes; and the mean module, or half the diameter, thirty minutes; our little module has twenty. See COLUMN.

MODULER, Fr. in *Mufic;* to modulate extempore is a refearch after new effects and new combinations. Learning, hand, and experience are neceffary to do credit to the performer, and pleafe and furprife the hearer. And we may add that a prelude, toccata, or voluntary by a great player, feems infpiration, and is worth a hundred pieces committed to paper.

MODULI CAMPANORUM, chimes. See Graffineau, p. 139, a long article on the fubject. See CARILLONS.

MODUNDAH, in *Geography*, a town of Bengal; 18 miles N.N.E. of Calcutta.

MODUS DECIMANDI is when a parcel of land, a fum of money, or a yearly penfion, belongs to the parfon, either by compofition or cuftom, time out of mind, in fatisfaction for tithes in kind: or, when there is by cuftom a particular manner of tithing allowed, different from the general law of taking tithes in kind, which are the actual tenth part of the annual increafe.

This is fometimes a pecuniary compenfation, as twopence an acre for the tithe of land; fometimes it is a compenfation in work and labour, as that the parfon fhall have only the twelfth cock of hay, and not the tenth, in confideration of the owner's making it for him: fometimes in lieu of a large quantity of crude or imperfect tithe, the parfon fhall have a lefs quantity, when arrived to greater maturity, as a couple of fowls inftead of tithe eggs, &c. In fhort, any means by which the general law of tithing is altered

altered, and a new method of taking tithes is introduced, is called a *modus decimandi*, or ſpecial manner of tithing. In order to make a good and ſufficient modus the following rules muſt be obſerved:

1. It muſt be certain and invariable. (1 Keb. 602.) 2. The thing given, in lieu of tithes, muſt be beneficial to the parſon, and not for the emolument of third perſons only. (1 Roll. Abr. 649.) 3. It muſt be ſomething different from the thing compounded for. (1 Lev. 179.) 4. One cannot be diſcharged from payment of one ſpecies of tithe, by paying a modus for another. (Cro. Eliz. 446. Salk. 657.) 5. The recompence muſt be in its own nature as durable as the tithes diſcharged by it; *i. e.* an inheritance certain. (2 P. Wms. 462.) 6. The modus muſt not be too large, which in law is called a *rank* modus. (11 Mod. 60.) In theſe caſes of preſcriptive or cuſtomary moduſes, the law ſuppoſes an original real compoſition to have been regularly made, which being loſt by length of time, the immemorial uſage is admitted as evidence to ſhew that it did once exiſt, and that from thence ſuch uſage was derived. Now time of memory hath been long aſcertained by the law, to commence from the reign of Richard I. and any cuſtom may be deſtroyed by evidence of its non-exiſtence in any part of the long period from his days to the preſent. Blackſt. Com. b. ii.

MODYPOUR, in *Geography*, a town of Hindooſtan, in Bahar; nine miles S. of Patna.

MODZIEN, a town of Perſia, in the province of Mazanderan; 48 miles S.W. of Aſtarabad.

MOËCKARN, a town of the duchy of Magdeburg; 16 miles E. of Magdeburg.

MOEDA. See MOIDORE.

MOEN, or MONA, in *Geography*, an iſland of Denmark, in the Baltic, ſeparated from the S. end of the iſland of Zealand, and from the N.E. coaſt of Falſter, by a narrow ſea, about 16 miles in length, and from three to five in breadth; containing one town, *viz.* Stoege or Stege, and ſeveral villages. N. lat. 55°. E. long. 12° 20′.

MOEN, or MÖN, a river which riſes in Weſtphalia, three miles N.W. of Brilon, paſſes by Rhuden, &c., and joins the Roer at Nehem.

MOENCHIA, in *Botany*, received its name from Ehrhart in memory of Conrad Moench, a profeſſor of botany at Heſſe Caſſel, author of the *Flora Haſſiaca*. Ehrh. Beitr. faſc. 2. 177. This genus conſiſts of only one ſpecies, *Sagina erecta*, Linn. Sp. Pl. 185. Sm. Fl. Brit. 200. Engl. Bot. t. 609. The only difference in the eſſential character conſiſts in the ſtructure of the capſule, which ſplits at the top into eight teeth, inſtead of ſeparating, more or leſs perfectly, into four valves, like other *Saginæ*. The habit of this elegant little plant muſt alſo be allowed to be diſſimilar to that of the genus with which it has always been aſſociated. See SAGINA.

MOERDA, See MURDER.

MŒRHINGIA, in *Botany*, was named by Linnæus in honour of Paul Henry Gerard Mœrhing, a German phyſician, in the duchy of Oldenburg, who was the author of various botanical tracts. His firſt treatiſe appeared in 1733, entitled the anatomy of vegetables, in which the apparent ſtructure of leaves, after being macerated in water, is particularly conſidered.—Mœrhing printed a catalogue of his own garden in 1737, and furniſhed afterwards ſeveral papers for the *Ephemerides Naturæ Curioſorum*. He died in 1792, at the advanced age of 82 years. Linn. Gen. 195. Schreb. 264. Willd. Sp. Pl. v. 2. 439. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 416. Juſſ. 300. Lamarck Illuſtr. t. 314.—Claſs and order, *Octandria Digynia.* Nat. Ord. *Caryophyllei*, Linn. and Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of four lanceolate, ſpreading, permanent leaves. *Cor.* Petals four, ovate, undivided, ſpreading, ſhorter than the calyx. *Stam.* Filaments eight, capillary; anthers ſimple. *Piſt.* Germen ſuperior, globoſe; ſtyles two, erect, the length of the ſtamens; ſtigmas ſimple. *Peric.* Capſule roundiſh, of one cell and four valves. *Seeds* numerous, roundiſh, convex on one ſide, angulated on the other.

Eſſ. Ch. Calyx inferior, of four leaves. Petals four. Capſule of one cell, and four valves.

1. M. *muſcoſa.* Linn. Sp. Pl. 515. Jacq. Auſtr. t. 449. (Alſine ſaxifraga anguſtifolia minima montana; Column. Ecphr. p. 1. 292. t. 290.)—Found growing in moſſy ſituations, near trickling rills, on mountains in the ſouth of Europe, flowering throughout the ſummer. *Root* perennial, thread-ſhaped and creeping. *Stems* annual, herbaceous, thread-ſhaped, round, ſlender, ſmooth, much branched. *Leaves* oppoſite, linear, very narrow, ſmooth, dilated at the baſe, ſo as to make the ſtem ſomewhat perfoliate. *Flowers* ſolitary, on long, erect, ſlender, axillary ſtalks. *Petals* ovato-linear, obtuſe, milk white. *Capſules* yellowiſh when ripe. *Seeds* eight or ten, kidney-ſhaped, dark-brown, furniſhed with a large, white, jagged border to their ſcar of inſertion.

MŒRIS, LAKE, in *Ancient Geography*, a lake of Egypt, concerning the ſituation and extent, and even the exiſtence of which, authors have differed. It has been repreſented as the nobleſt and moſt wonderful of all the works of the kings of Egypt; and accordingly Herodotus conſiders it as much ſuperior to the pyramids or labyrinth. As to its ſituation, Herodotus (lib. ii.) and Strabo (lib. xvii.) mark it out by placing the labyrinth on its borders, and by fixing the towns, which were round it, ſuch as Achantus to the ſouth, Aphroditopolis towards the eaſt, and Arſinoé to the north: Diodorus Siculus (lib. i.) and Pliny (lib. v.) confirm theſe authorities, by placing it at 24 leagues from Memphis, between the province of that name and that of Arſinoé. If the lake, like that of Mareotis, had totally diſappeared, doubts as to its ſituation might ſtill have been entertained; but the poſition marked by the above-mentioned hiſtorians leads us to a lake, actually exiſting, known by the name of BIRKET *Caroun*, (which ſee,) more than 50 leagues in circumference. With regard to the extent of this lake, we recur again to the teſtimonies above cited: Herodotus ſays, that the circumference of the lake Mœris was 3600 ſtadia, or 60 ſchenes, which, ſays the hiſtorian, form the dimenſions of the maritime baſe of Egypt, (75 leagues.) He adds, that it ſtretches from N. to S. and that its greateſt depth is 300 feet. The hiſtorian has fixed the meaſure of the ſchene in Lower Egypt at four miles, or 1¼ league, ſo that the 60 ſchenes make 75 leagues. If we compare the meaſures by Strabo and Diodorus Siculus, we ſhall find that the baſe of Egypt was eſtimated at 75 leagues, and hence it will follow, according to the account of Herodotus, that the lake was in circuit 75 leagues. Some writers, who have taken the uſual meaſure of the ſtadium at 100 toiſes, have aſſigned to this lake a circumference of 150 or even 180 leagues. But as the hiſtorian has determined the meaſure of 3600 ſtadia to be 60 ſchenes, or 75 leagues, he muſt have made uſe of ſtadia of 50 toiſes each. Boſſuet, the biſhop of Meaux, has vindicated the ſtatement of the largeſt extent of 180 leagues, which Voltaire has treated with raillery; and M. Rollin, conceiving it to be incredible, adopts the opinion of Pomponius

nius Mela, who says, that this lake is but 20,000 paces, that is, seven or eight French leagues in circumference. Pliny estimates it at 250,000 paces, or about 80 leagues. M. d'Anville, with a view of conciliating the different contending parties, has, in his map of Egypt, marked a great canal, to which he gives the name of the lake Mœris. The depth of 300 feet ascribed to this lake by historians must be exaggerated; but perhaps less so than we may be led to imagine. The bottom which it occupies is a bason, formed by the mountains. It is very low, since the Nile runs into it even by the canal of Tamieh. Although the mud may have gradually collected in a series of ages, its depth is still very considerable. Two pyramids, says Herodotus, constructed in an island towards the middle of the lake, rise from 300 feet below the water, and are as high out of it. Each of them has on its summit a colossal statue, seated on a throne. Their total elevation, taken from the base, is a stadium of 600 feet; thus marking the measure of the stadium, as he had before, in giving the circumference of the lake, reduced it to 50 toises. These pyramids no longer exist; nor indeed did they exist in the time of Augustus, for they are not mentioned by Strabo. Lake Mœris, says Herodotus, occupies a soil very dry, and destitute of springs. It derives its waters from the Nile, which runs into it during six months; and during the remainder of the year it restores them to the river. During the former period, the fishery produces a talent of silver daily to the royal treasury, and 20 minas only during the latter. According to the natives of the country, a canal is pierced across the mountain, the extended chain of which commands Memphis. This is an outlet by which the superfluous waters are poured into the sands of Libya on the western side. As for the earth that was taken from the lake, the historian was informed, that it had been conveyed to the river, and carried by the current into the sea. According to the account of Strabo, the province of Arsinoé contains the wonderful lake of Mœris, which resembles the sea in its extent, its colour, and its shores. As deep as it is extensive, it receives at the beginning of the inundation the waters which would otherwise cover the harvests and the habitations of men; they are conducted thither by a large canal. When the Nile subsides, they return by two other canals (those of Tamieh and of Bouch), which, as well as the former, serve for watering the fields, which is naturally performed. At the head of the canals sluices are formed, which are opened at pleasure; whether to introduce or to let off the waters.

At present this lake is only about 50 leagues in circuit; but this diminution by no means proves that Herodotus and Pliny were deceived in their calculations. Considering the revolutions to which Egypt has been subject for a series of 2000 years, it might have undergone still greater changes. The noble design of forming this lake is said to have been conceived by one of the Pharaohs, called Mœris, and he determined to change a part of the country, which was sandy and desert, into an useful lake. After the excavation had been made by the labour of some thousands of men, and at an immense expence, he drew a canal 40 leagues in length, and 300 feet wide, for the purpose of conducting thither a part of the waters of the Nile. This great canal, which still subsists entire, is known under the name of "Bahr Jousseph," Joseph's river. It opens near "Tarout Eccherif," and ends at "Birket Caroun." As in several places this canal was cut out of the rock, the labour and expence must have been very great. It was not sufficient to have disengaged Egypt from the excess of the inundation, which in those remote ages remained too long on the lands, at that time lower than they are in our days, and occasioned its sterility; it was necessary also to render these waters useful to agriculture. This great prince succeeded in doing this by drawing two other canals from the lake to the river. At their opening were formed two sluices, which were kept shut during the increase of the Nile; then the waters conveyed by the canal of Joseph were heaped up in the immense inclosure of lake Mœris, encompassed with dykes and mountains. During the six months that the Nile was on the decline, these sluices were opened, and a surface of water of about 80 leagues in circumference, and 30 feet higher than the ordinary level of the river, formed a second inundation to be directed at pleasure. One part returned to the Nile, and served for the navigation. The other part branched out into innumerable rivulets, watered the fields, and diffused fertility even to the very sandy hills. This great work supplied the deficiency of water in years of a moderate overflow, by retaining those precious waters, which otherwise would have flowed uselessly to the sea. Its benefits were still more strongly marked in the time of a great inundation. It received that hurtful superfluity of them, which would have prevented the sowing of the earth. Lest this artificial sea should break down the barriers that were opposed to it, and cause frightful devastation in the country, a canal was cut through the mountains, by which the superfluous waters were poured into the sands of Libya. At present this lake has lost almost all its advantages. From the period of nearly 1200 years, since which Egypt has fallen into the hands of barbarous nations, they have either destroyed, or suffered to perish, the chief part of these monuments. The Mareotis is dried up, the canal of Alexandria is no longer navigable, and the Mœris is only 50 leagues in circumference. If the canal of Joseph were cleared out, where the mud is collected to a vast height, if the ancient dykes were re-established, and the sluices of the canals of Tamieh and of Bouch restored, lake Mœris would still serve the same purposes. It would prevent the devastation, of the too great swellings of the rivers, and supply the deficiency of those which are inadequate. We should see it, as on former occasions, extending itself from Nesle and Arsinoè to the Libyan mountains, and offering to the view of the astonished traveller, a sea formed by the hand of man. Rollin's Anc. Hist. vol. i. Savary's Letters in Egypt, vol. i.

MOERSBERGEN, in *Geography*, a town of Holland, in the department of Utrecht; 10 miles E. of Utrecht.

MŒSIA, called by the Greeks *Mysia*, in *Ancient Geography*, a country of Europe, lay N. of Macedonia and Thrace, and extended from S. to N. as far as the right bank of the Danube. From W. to E. it extended from Pannonia, where the Drinus (Drin), passing to Sirmium and Singidunum (Belgrade), in order to discharge itself into the Danube, served for its boundary: to the W., comprehending the territory called "Pontus-Euxinus," from the promontory called "Hæmi-Extrema," and to the S. as far as the Istropolis. This large extent of country was divided into two distinct territories, partly by the mountains, and partly by the river Cebrus (Zebris), which discharged itself into the Ister. The part comprehended between the Drinus and the Cebrus was called "Mœsia Superior," and that which extended from the Cebrus to the sea was called "Mœsia Inferior;" *i. e.* Upper and Lower Mœsia. The principal river of Upper Mœsia was the Margus (Morava), formed of two other rivers; and farther to the E. it had the Tinacus (Timak). The principal towns were Singidunum (Belgrade), Viminacium (Minas), Bononia (Vidin), and Ratiaria (Artzar). In the interior of the country is Neissus,

Neissus (Nissa); besides other places mentioned by Ptolemy. The principal rivers of Lower Mœsia were the Œscus (Esker), the Osmus (Osmo), the Utus (Vid), the Iatrus (Jantra), all which rivers ran from S. to N. and emptied themselves into the Danube: the Panysus ran from W. to E., and discharged itself into the Euxine sea, near Odessus (Vasna). The principal towns are, upon the Danube, Œscus (Artzar), Nicopolis (Nicopoli), Durostom (Dristra or Silistria), Axopolis (Rassovat), and Trasmi. In the interior country were Sardica or Triaditza, near Sophia, Tauresium, the birth-place of Justinian, called Justiniana prima (Dginstendil), Nicopolis ad Hæmum (Ternova), Nicopolis ad Iatrum (Nicopi), and Marianopolis (Marienopoli). Upon the coasts of the Euxine sea, in the part called Scythia, and S. of this part, were Tomi (Temeswar), the place of Ovid's exile, Caria (Kalgri), and Odessus (Varna).

MOESKIRCH, in *Geography*, a town of Germany, and capital of a lordship, belonging to the princes of Furstenburg; 18 miles N. of Constance. N. lat. 47° 59′. E. long. 9° 14′.

MOESTLIN, Michael, in *Biography*, a German Lutheran divine, and celebrated mathematician, who flourished in the 17th century, was born at Goppingen, in the duchy of Wirtemberg. He obtained the friendship and patronage of the duke, who sent him to the university of Tubingen, where he was quickly distinguished by his diligence and talents, and took his degrees. After this he embarked in the ministry, was chosen pastor of the town of Tetschen, and discharged the duties of his office to the satisfaction of his flock, and acquired universal respect by his unaffected piety and exemplary manners. He also obtained considerable reputation for profound skill in the mathematics, for which he had a sort of natural turn. On this account he was elected mathematical professor at Heidelberg, where he remained about three years, and then returned to Tubingen. Here he was appointed to the mathematical chair, in which he continued during the remainder of his life. He died in 1650. He is said to have been the first person who explained the cause of the pale light observable on the disk of the moon a little before and after the change. In Italy he delivered an harangue in defence of the Copernican system, and is thought to have influenced Galileo in renouncing the old hypotheses, and in embracing the system which has now obtained a sure footing. He published "Ephemerides," and several other works connected with science. Moreri.

MŒURS, Fr. morals, manners. Rousseau has treated this word as a musical term; and informs us that it constituted a branch of Greek music, under the title of "Hermosmenon," which consisted in knowing how to choose what was most beautiful and proper in each genus, without permitting musicians to give to each object and each character all the forms of which it was susceptible; but obliged them to confine themselves to what was most appropriate to the subject, the occasion, the persons, and the circumstances. The morals consisted further in so arranging and proportioning all the constituent requisites in musical composition, such as the mode, the time, the rhythm, melody, and even the transitions; so that in the entire piece there should be a conformity and agreement which left no disproportion; but that all its several parts should constitute one perfect whole.

To prescribe to what point of perfection an art should be carried, and reduce to rules what is decorous, fitting, and excellent, was a degree of refinement to which the moderns pretend not to have arrived.

MOEY, in *Geography*, a small island in the East Indian sea. S. lat. 5° 50′. E. long. 132° 50′.

MOFFAT, a large village in the county of Dumfries, Scotland, is situated upon the banks of the river Annan, at the distance of fifty miles south-west from Edinburgh, and is distinguished chiefly as the most celebrated watering place in the northern division of our island. It stands upon a considerable eminence, encompassed on the east, west, and north sides by hills of different heights, some of which are inclosed and cultivated, and others laid out as pasture lands. A fine holm, or valley, extends to the south, carrying in its bosom the limpid stream of the Annan. The principal street, declining in the direction of this vale, commands a charming view of it, for the space of several miles. The houses here are for the most part well built, and the streets are kept exceedingly clean and smooth; and from their height and gravelly foundation dry so rapidly, that in an hour after the heaviest rain, the inhabitants may promenade without the smallest inconvenience. There is one capital inn in the village, where the post-office is kept, and several lesser ones, as well as excellent lodging-houses, fit for the reception of the most genteel families. Here are an assembly-room and a bowling-green.

The Moffat Well is situated about a mile and a half from the village, having an excellent carriage road leading to it, and a long room, stables, and other conveniences for the accommodation of the company when they are stationed there. The valuable medicinal properties of this well were first discovered about 160 years ago; since which time it has been constantly held in great estimation. Its waters are powerfully diuretic, and generally allowed to be effectual in the cure of scurvy and scrophula, if the patient's lungs are not injured previously to the use of them. When poured into a glass the water sparkles like champagne, and is so extremely volatile that it cannot be drank in perfection, unless at the fountain. According to the late Dr. Garnet, who paid considerable attention to this subject, when analysed, it is found to contain of muriat of soda (common salt) 36 grains; sulphuretted hydrogen gas 10 cubic inches; azotic gas 4 ditto; carbonic acid 5 ditto.

At the distance of four miles from Moffat, is another mineral spring, called the Hartfell Spaw, because issuing from a rock of alum-slate in a tremendous ravine, on the side of a mountain of that name. The chief mineral substances of this water are the sulphats of iron and alumina, which give it a powerful tonic quality. It is principally used, therefore, in cases of weakness; but has likewise been found serviceable in tetterous complaints and obstinate old ulcers. This well is honoured with high encomiums by Dr. Johnson. Several other chalybeate and petrifying springs have been discovered in the country adjacent to this village. One at Evan-bridge is equal in strength to the wells at Harrowgate, but it has hitherto been entirely neglected.

The vicinity of Moffat is no less fruitful in remains of antiquity than in salubrious springs. Part of a Druidical temple is still visible close to the bank of a rivulet which passes out of a small lake, and falls into the water, deriving its name from the village. Near this spot are likewise vestiges of a Roman road; and several stations and encampments of that people. A piece of gold was found a few years ago in a moss adjoining to the road, which is supposed to have formed part of some military ornament. Its outer edge was adorned with a border, in which were the following letters formed by cutting through the interstices, IOV. AVG. VOT. XX. Vestiges of a British encampment may be seen about three miles south-east from the village. On the road between it and the well is a large mound, of of a conical form, with a very deep ditch round it: another of smaller dimensions stands at the distance of a few hundred yards. A mile east from the Roman road are two caves, cut out of free-stone rock; they are of a large size, but by whom formed, or for what purpose, it is difficult to conjecture. Many ruins of old towers are visible in this parish, as well as in the adjoining one of Kirkpatrick-juxta; some of which are placed in small enclosures, defended by walls and ditches. Among the more remarkable of the entrenched parks, as they are called, is the park of Achencass, where the walls measure 15 feet in thickness, and upwards of 20 in height.

According to the parliamentary returns of 1801, the resident population of this parish amounted to 1619 persons, viz. 748 males, and 871 females. Sinclair's Statistical Account of Scotland.

MOFFEN ISLAND, in *Geography*, an island in the North sea, N. of Spitzbergen; it is of a round form, about two miles in diameter, with a lake or large pond of water in the middle, and between this lake and the sea the ground is from half a cable's length to a quarter of a mile broad: the whole island, besides this pond, is covered with gravel and small stones, without the least verdure or vegetation of any kind. The navigators of the Carcass, who visited this island, saw only one piece of drift wood, about three fathoms long, with a root on it, and as thick as the ship's mizen-mast, which had been thrown up near the high part of the land, and lay upon the declivity towards the pond. They also saw there bears, and a number of wild ducks, geese, and other sea-fowls, with bird's nests all over the island. They found an inscription over the grave of a Dutchman, who was buried there in July 1771. The tide seemed to flow eight or nine feet, and a current was found which carried the ship to the N.W. from the island, but which before carried it to the S.E., at the rate of a mile an hour, towards it. On the W. side is a fine white sandy bottom, from two fathoms, at a ship's length from the beach, to five fathoms, at the distance of half a mile. It is remarked, as surprising, that no notice should be taken of this island by the old navigators; unless it may be supposed that it did not then exist, and that the streams from the great ocean up the W. side of Spitzbergen, and through the Waygat's shoals, meeting here, raised this bank, and occasioned the quantity of ice that generally blocks up the coast in its vicinity. N. lat. 80° 5'. E. long. 12° 30'. Phipps's Voyage towards the North Pole.

MOFHAK, a small town of Arabia, in the province of Yemen, situated on the summit of a steep hill. This town has a dola. The revenue of the town, and of the territory annexed to it, is enjoyed by one of the Imam's sons. Mofhak lies in the route from Sana to Beit el Fakih.

MOGADOR, or MOGODOR, called also by the Moors *Suera*, a town of Morocco, in the province of Hea, which received its name from a saint, held here in great veneration, by the name of Sidi Mogodor, whose tomb is to be seen at a small distance to the south of the town. It had formerly a wretched castle, built by the Portuguese, to preserve a communication with their settlements to the south of this coast; and also to protect the entrance of a harbour, formed by a channel between the main land and a small island. The situation appearing favourable for a place of trade, the emperor resolved to found a city here; and the wealthier Moors began to build houses, to gratify the wishes of their sovereign. Foreign merchants were invited to do the same; and with a view of inducing them to comply with the emperor's wishes, large abatements were offered in the custom duties; but promises to this purpose were not very scrupulously observed. This city was begun in 1760, and has since been completely finished. It contains a great number of houses, handsomely and solidly constructed. The streets are all straight lines, and there is no town in the empire in which a regularity of plan is so strictly observed. It is surrounded with walls, and batteries are erected, not only on the sea-side, but towards the land, to defend it from any incursion of the southern Moors. The emperor has brought all the European merchants to settle at Mogodor, and, notwithstanding its distance from Europe, it is the only port on the coast which maintains a continual commercial intercourse with that quarter of the world. This city stands on marshy ground, and so low, that, at spring-tides, it is almost surrounded by the sea. The country about it is a melancholy desert of accumulated sand. The Europeans, however, have the advantage of a more easy communication with the southern provinces, which, by exchanging their productions for the commodities of Europe, render the trade of this place very flourishing. The port of Mogodor is formed by a channel between the main land and an island more than a mile in length. The entrance of this channel is to the north-west, and its outlet to the south. It is sufficiently large for ships of a middling size, but in general it has not sufficient depth; and this disadvantage is daily increased by the accumulation of sand. The number of ships which have been lost in this port in winter, by violent storms from the south-west, sufficiently prove how very dangerous it is in bad weather; 80 miles S.W. of Morocco. N. lat. 31° 30'. W. long. 9° 30'. Chenier.

MOGADOURO, a town of Portugal, in the province of Tras-los-Montes; 22 miles S.W. of Miranda di Duero.

MOGAMI, a town of Japan, in the island of Niphon; 110 miles N. of Jedo.

MOGANOOR, a town of Hindoostan, in Bahar; 11 miles S. of Namacul.

MOGARO, an island in the gulf of Venice, near the coast of Friuli. N. lat. 45° 47'. E. long. 31°

MOGATA, a town of Sweden, in East Gothland; 7 miles E. of Soderkioping.

MOGGIO, in *Commerce*, an Italian corn measure, which at Florence contains 8 sacchi, or 24 staja; the stajo being 4 quarti, 16 metadeli, or 32 mezzete: the moggio contains about 16 English bushels. At Leghorn, a moggio contains 2 rubbi, or 7½ sacchi; a sacco, 3 staja, or 384 bussoli. A sacco of good wheat weighs about 168 lb. of Leghorn, and contains 3720 French, or 4503 English cubic inches; so that 43 sachs of Leghorn are equal to 90 English bushels. See Tab. XXXI. under the article MEASURE.

MOGGURAH, in *Geography*, a town of Bengal; 8 miles N.W. of Goragot.

MOGHOSTAN, the denomination by which the southern part of the province of Kerman, in Persia, is distinguished.

MOGILEV, a town of Russia, and capital of a government, on the river Dnieper. The town is handsome and commercial, and a place in which the Russians carry on a considerable trade. It was taken from the Russians by the Poles in 1662; and by the division of Poland, in the year 1773, it was ceded to Russia, with its territory, and erected into an archbishopric of the Roman church, with an assistant bishop; 340 miles E.N.E. of Warsaw. N. lat. 53° 52'. E. long. 30° 14'.

MOGILEVSKOE, a government of Russia, bounded on the north by the government of Polotsk, on the north-east by that of Smolensk, on the south-east by that of Novgorod Sieverskoe, on the south by that of Tchernigov, and on the west by Poland; about 176 miles in length, in its widest breadth 120, in the north part 68, and in the south only 24. N. lat. 52° to 55°. E. long. 29° to 33°.

MOGILNICA, or MOULNICZA, a town of the duchy of Warsaw; 36 miles E. of Rawa.

MOGIMERI, a town of Brazil, in the government of St. Paul; 35 miles E. of St. Paul.

MOGLA, or MULLA, a town of Asiatic Turkey, and principal place of a Sangiacat, in Natolia, on the ruins of the Alinda; 100 miles S.E. of Smyrna. N. lat. 37° 8'. E. long. 28° 22'.

MOGLE, a town of Bosnia; 35 miles E. of Banjaluka.

MOGNA, a town of Italy, in the Feltrin.

MOGO, a town of Persia, in Laristan, on the coast of the Persian gulf; 40 miles W. of Lundsje.

MOGONTUEVSKOI, a town of Russia, in the government of Irkutsk, on the borders of China; 60 miles S.S.E. of Dorouinsk.

MOGORIN, in *Botany*, a name given by the Portuguese to an Indian or Chinese flower, growing on a small shrub. It is of a wonderful white colour, and not unlike the *ginseng*, only that it abounds more with leaves, and smells much sweeter; one single flower filling a whole house with its odoriferous effluvia. On this account the Chinese put a high value upon it, and carefully defend the shrub it grows on from the inclemency of the winter, by covering it with vases provided on purpose.

MOGORIUM, a name of barbarous origin, applied by Jussieu, *Gen.* 106, to such of the Linnæan species of *Nyctanthes*, as have a pulpy fruit, the calyx and corolla of such being presumed to have at least eight divisions; and the real *Nyctanthes*, being agreed to have a dry capsular fruit, besides other marks of distinction. Sir Joseph Banks and Dr. Solander have referred all the above-mentioned species to JASMINUM, (see that article,) in which they have been followed by Vahl and Willdenow. The measure is justified by the variableness of number in the parts of these flowers, even on the same individual plant, and the strong generic affinity between them all, independent of number. Such as have naturally a five-cleft flower, very commonly acquire one, two, or three additional segments; and those which have naturally eight, as *J. Sambac*, are liable to have twelve or more, without any obliteration of their organs of impregnation. When the latter takes place, the divisions of the corolla become greatly multiplied, as in other common instances.

MOGRABIANS, MOGARBA, or *Men of the West*, in *Military Language*, a name given to the infantry of the Turks, composed of the peasants of Tunis, Algiers, and Morocco, who have thought proper to seek in Syria and in Egypt that respect which is denied them in their own country. All the accoutrements and baggage of these soldiers are confined to a rusty firelock, a large knife, a leathern bag, a cotton shirt, a pair of drawers, a red cap, and sometimes slippers. Their pay is 5 piastres (about 10*s.* 10*d.*) *per* month, out of which they are obliged to furnish themselves with arms and clothing. They are maintained at the expence of the pacha, &c.

MOGUAR, in *Geography*, a town of Spain, in the province of Seville, at the mouth of the Tinto; 43 miles W. of Seville. N. lat. 37° 12'. W. long. 6° 58'.

MOGUL EMPIRE, in an extensive sense, denotes that empire of Asia, over which Tamerlane and his immediate successors reigned, and in which India was not included; but in a more restricted sense, it signifies, as custom has in later times appropriated the name, that empire which was held by the descendants of Tamerlane in Hindoostan and the Deccan. The origin of the Mogul empire is so far remote, that it is difficult to distinguish between fabulous tradition and the records of authentic history. It probably arose from small beginnings, and extended itself by the conquests of ambitious princes. It appears, however, to have been of very limited extent, if indeed it existed at all under this appellation, when Temujin, better known under the name of Jenghiz Khan, or Gengiz Cawn, made his appearance. The birth of this conqueror is referred to the year 1163; and at the time of his father's death, his subjects are said to have amounted to between 30,000 and 40,000 families: but a majority of these revolted, and in the earlier part of his life and reign he was left almost without any subjects. He rose, however, into notice and power, under the protection of Vang Khan, who was sovereign of a considerable number of Tartar tribes, situated to the north of Kitay, or China, and who has been known among Europeans by the name of Prester John. Thus encouraged and aided, he subdued those subjects who had revolted in the year 1201, and was able to keep possession of his throne. It was not long, however, before Vang Khan became jealous of the growing power, and perhaps manifest ambition, of Temujin, whom he had made his general; so that he contrived treacherous measures for destroying a prince, whom he considered as his rival. This disagreement terminated in an open war, which Temujin prosecuted with success. Vang Khan was defeated in a battle, by which he lost 40,000 men; and soon after was ungenerously put to death by the father-in-law of Temujin, to whom he had fled for refuge. The conqueror seized on the dominions of the vanquished Khan, and rapidly extending his marches and victories, reduced all the Mogul tribes in the year 1205. In a diet, held in the spring of the following year, to which all the great lords both of the Moguls and Tartars were summoned, the Mogul empire was confirmed to him and his successors, together with those kingdoms which he had subdued, and he was solemnly proclaimed emperor. During his inauguration, a prophet is said to have appeared in the assembly with a divine message, declaring that from this time Temujin should assume the name of "Jenghiz Khan, or the most great khan of khans;" and at the same time predicting, that his posterity should be khans from one generation to another. Thus established on the throne, and held in the most profound veneration by his subjects, he projected the extension of his dominions by more conquests. He began with the emperor of Hya, the western part of the empire of Kitay, and in 1209 compelled him to become his tributary: and when, in 1210, an acknowledgment of his being tributary to the emperor of Kitay was demanded of him, he resisted the demand, the consequence of which was a war, that terminated in the dissolution of the Kitay empire. In the year 1216 he resolved to carry his arms westward, and, in his progress, defeated an army of 300,000 Tartars, who had revolted; and in 1218 he deputed ambassadors to express his desire of an alliance with Mohammed Karazm (Charasm) Shah, emperor of Gazna or Ghizni. Although the alliance was concluded, it was soon treacherously violated; and this event occasioned a war, which in 1221 accomplished the conquest of the empire of Ghizni, and thus terminated the dynasty of Charasm. Jenghiz Khan, however, left Hindoostan undisturbed. After the reduction of Charasm, some of the Moguls marched into Iran or Persia, where they made extensive conquests; and others invaded Georgia, and the countries lying west of it, committing in their progress the most atrocious enormities. In 1225 Jenghiz Khan returned to Hya, slew the emperor, and destroyed

ſtroyed the country. But this was the laſt exploit of this ambitious and ſavage conqueror, who died in 1227, as he was marching to complete the deſtruction of the Chineſe. At the death of Jenghiz Khan, the Mogul empire extended over a prodigious tract of country; being, as it has been ſaid, more than 1800 leagues in length from eaſt to weſt, and upwards of 1000 in breadth from north to ſouth. The ſucceſſors of Jenghiz Khan, urged by an inſatiable ambition, purſued the ſame plan of conqueſt; ſo that Oktay was acknowledged emperor after Jenghiz, and had under his immediate government Moguleſtan, or the country of the Moguls properly ſo called, Kitay, and the countries to the eaſt of the Tartarian ſea. His brother Jagaty governed under him a great part of the weſtern conqueſts. The country of the Kipjacks, and others to the eaſt and north-eaſt, north and north-weſt, were governed by Batu or Patu, the ſon of Juji, who had fallen in the wars; while Tuli or Tolay, another ſon of Jenghiz Khan, had poſſeſſion of Khoraſan, Perſia, and that part of India which had been conquered. On the eaſt ſide the Mogul arms prevailed, and ſubdued not only the empire of Kitay, but the ſouthern part of China. In the year 1254, Magu, or Menkho, the fourth khan of the Moguls, raiſed a large army, and gave the command of it to his brother Hulaku, or Hulagu, for the purpoſe of extending his dominions towards the weſt. With this army, in 1255, he invaded Iran, ſuppreſſing the Iſmaelians or Aſſaſſins; and two years afterwards he advanced to Bagdad, which he captured. Cruelty and devaſtation marked the footſteps of the Moguls; fire and ſword were the implements of their warfare; and it is ſaid, that in Bagdad, and its vicinity, the number of ſlain amounted to 1,600,000. In the following year he invaded Syria, took poſſeſſion of Damaſcus without reſiſtance on the part of the inhabitants, whoſe lives were therefore ſpared; and having captured Aleppo by ſtorm, murdered the inhabitants, without ſparing even the children in their cradles. Theſe cities, which in the ſucceeding year revolted, were again taken by the Moguls and plundered, and the inhabitants were either ſlaughtered without mercy, or carried into ſlavery. Hulaku died in 1264; and at the time of his deceaſe we may fix the greateſt extent of the Mogul empire. It comprehended the whole of the continent of Aſia, excepting part of Hindooſtan, Siam, Pegu, Cochinchina, and a few of the countries of Leſſer Aſia, which the Moguls had not attacked. From this period, however, this vaſt and overgrown empire began to decline. The ambitious khans failed in their attempts upon Japan and Cochinchina, and alſo upon Hindooſtan; and the empire itſelf was divided into ſeveral ſmaller partitions. The governors of Perſia, being of the family of Jenghiz Khan, owned no allegiance to any ſuperior; thoſe of Tartary purſued the ſame courſe; the Chineſe threw off the yoke: and thus the continent of Aſia aſſumed, in a great degree, the ſame aſpect which it had before Jenghiz Khan began his conqueſts. At length, in the year 1369, Timur Bek, or Tamerlane, one of the petty princes of this broken empire, having conquered a number of others, was crowned at Balk, with the pompous title of "Sakeb Karan," *i. e.* the emperor of the age and conqueror of the world. He began his reign with the exerciſe of various cruelties.

In 1370, Timur croſſed the Sihon, made war on the Getes, and attacked Charaſm. In 1379 he had fully conquered the country of the Getes, as well as Khoraſan; and from that time he purſued his conqueſts, as Jenghiz Khan had done, though with leſs cruelty. In 1387, he had reduced Armenia, Georgia, and the whole of Perſia; the conqueſt of which laſt country was completed by the reduction of Iſpahan; 70,000 of the inhabitants of which city were ſlaughtered on account of the ſedition of ſome diſaffected perſons. After the reduction of Perſia, Timur turned his arms northward and weſtward, ſubduing all the countries as far as the Euphrates. He took the city of Bagdad; reduced Syria; and having ravaged a great part of Ruſſia, returned in 1396 to Perſia, where he made a ſplendid feaſt for his whole army. After ſeveral irruptions which had been made by the Moguls into Hindooſtan, after the death of Jenghiz Khan, Timur, who had already extended his empire over all the weſtern Aſia and Tartary, turned his arms towards this country in 1398. In the preceding year he had ſent his grandſon Peer Mahomed to reduce the Panjab and Moultan, and in October croſſed the Indus himſelf; and joining his grandſon near Moultan, his army proceeded in different diviſions to Delhi, which ſubmitted without what may be properly termed a battle. The maſſacres and exterminations that ſucceeded his taking poſſeſſion of the city, were executed under his immediate direction; and juſtly entitled him to the appellation of the "deſtroying prince." Timur ſtaid in Delhi only 15 days; and then appears to have been on his return to the ſeat of his empire, when, hearing of a fortreſs in the Dooab that had reſiſted the arms of a former Mogul invader, he marched towards it and took it. From thence he proceeded to the place where the Ganges iſſues out of the mountains, and where the Hindoos reſort at certain ſeaſons, in vaſt numbers, to pay their adorations to, and to purify themſelves in, that ſacred ſtream. His object was the extermination of theſe inoffenſive people; and he partly ſucceeded. From this place, turning to the N.W., along the foot of mount Sewalick, he continued his maſſacres, though not without oppoſition, until he arrived on the frontiers of Caſhmere. He ſpent little more than five months, between the time of his croſſing and recroſſing the Indus, and in doing this he paid greater attention to the ſeaſons than Alexander had done. Timur, however, may be ſaid rather to over-run than to conquer or ſubject; for he did not diſturb the order of ſucceſſion in Hindooſtan, but left Mahmood on the throne; reſerving to himſelf the poſſeſſion of the Panjab country only; which his ſucceſſors did not long retain. His views were at this time directed towards the Turkiſh empire; and this circumſtance induced him to neglect India, which did not promiſe ſo plentiful a harveſt of glory as the other. During his life, which terminated at Samarcand in the year 1405, he was prayed for in the moſques of Hindooſtan, and the coin was ſtruck in his name; but this might be more the effect of policy in the uſurpers of Mahmood's throne than the act of Timur. On Timur's death his empire fell into great diſorder, and was diſtracted by civil wars, till at length peace was reſtored by the ſettlement of Shah Rukh, Timur's ſon, on the throne. The empire ſubject to his dominion was much reduced; Charaſm, Khoraſan, Candahar, Perſia, and part of Hindooſtan being the countries of which it conſiſted. By him his dominions in this reduced ſtate were tranſmitted to his ſon Ulug Beg, well known by his aſtronomical tables. A ſucceſſion of princes filled up the interval till the death of Abuſaid Mirza, a lineal deſcendant of Timur. From this time we may conſider the empire of Timur as diſſolved, though his deſcendants ſtill reigned in Perſia and Hindooſtan.

The conqueſt of Hindooſtan was effected by Sultan Baber, a deſcendant of Timur or Tamerlane, and Jenghiz Khan. This prince reigned over a kingdom compoſed generally of the provinces ſituated between the Indus and Samarcand. Being diſpoſſeſſed of the northern part of his dominions by the Uſbecs, he determined to try his fortune in Hindooſtan, whoſe diſtracted ſtate under Ibrahim II. in 1516, encouraged his

hopes

hopes of conqueſt. His firſt expedition from Cabul, where he reſided, acroſs the Indus, was undertaken in 1518; this was ſucceeded by four others; and in the fifth (A.D. 1525), he defeated the emperor of Delhi, and put an end to the dynaſty of Lodi. He reigned only five years in Hindooſtan, chiefly employing himſelf in the reduction of the eaſtern provinces. It was in the perſon of Baber that the line of Tamerlane firſt mounted the throne of Hindooſtan; and it was in that of Acbar, his grandſon, that it was eſtabliſhed. The conqueſt of their anceſtor, about a century and a half before, had no ſhare in effecting the preſent ſettlement. Baber was, in reality, the founder of the Mogul dynaſty; and from this event Hindooſtan derived the appellation of the "Mogul empire." The princes of the houſe of Timur have ſince their firſt eſtabliſhment on the throne eagerly purſued the conqueſt of the Deccan, not conſidering that this region, which poſſeſſed ample reſources within itſelf, and innumerable advantages in point of ſecurity from an enemy without, was alſo ſituated at ſuch a diſtance from the capital, as to hold out to its viceroy the temptation of independence whenever a favourable opportunity offered. Perhaps, ſays major Rennell, if the Deccan had been originally left to itſelf, the poſterity of Timur might ſtill have ſwayed the ſceptre of Hindooſtan. In proceſs of time the Mogul empire became merely nominal; and the emperors were regarded as of no political conſequence, otherwiſe than as their names and perſons are made uſe of by different parties to forward their own views. The Mogul empire attained its full meaſure of extent under the reign of Aurungzebe, ſee his article. In this empire many parts of it were 1000 miles diſtant from the ſeat of government; and accordingly its hiſtory is one continued leſſon to ſovereigns, not to graſp at too much dominion, and to mankind to circumſcribe the undertakings of their rulers. Rennell's Memoirs, Introd. See DECCAN, DELHI, and HINDOOSTAN. See alſo MONGOLES.

MOGULISTAN, or MOGOLISTAN, the country of the Mogul Tartars. In a larger ſenſe, this term comprehends the whole of Tartary, from the Caſpian to the North Atlantic; but, in a more reſtricted ſenſe, to an extenſive tract of country between Bucharia and China, north of Thibet. See MOGUL *Empire* and MONGOLES.

MOGULMARY, a town of Bengal; 18 miles S. of Burdwan.

MOGULPOUR, a town of Hindooſtan, in the circar of Schaurunpour; 36 miles S.S.W. of Schaurunpour.

MOGULPURRAH, a town of Hindooſtan, in Bahar; 18 miles N.N.W. of Bahar.

MOGULS. See MONGOLES.

MOGULSERAI, a town of Hindooſtan, in Benares; 10 miles S.E. of Benares.—Alſo, a town of Hindooſtan, in the circar of Sirhind; 15 miles N.N.E. of Sirhind.—Alſo, a town of Hindooſtan, in the country of Agra; 24 miles N.N.W. of Kerowly.

MOGURANI, a town of Walachia; 48 miles N. of Buchareſt.

MOGWITZ, a town of Sileſia, in the principality of Neiſſe; 6 miles N.N.E. of Ottmuchau.

MOGYESZO, a town of Hungary; 12 miles W. of Tokay.

MOHACS, a town of Hungary, on the Danube; 56 miles W. of Zegedin. N. lat. 46° 2′. E. long. 18° 44′.

MOHADAN, AL, a town of Arabia, in the province of Hedsjas; 80 miles E. of Madian.

MOHADY, a town of Hindooſtan, in Berar; 31 miles E.N.E. of Nagpour.

MOHAIR, in *Commerce*, the hair of a kind of goat, frequent about Angora in Turkey; the inhabitants of which city are all employed in the manufacture of camblet made of this hair. See CAMBLET and CAPRA *Angorenſis*.

Some give the name mohair to the camblets or ſtuffs made of this hair: of theſe there are two kinds; the one ſmooth and plain; the other watered like tabbies: the difference between the two only conſiſts in this, that the latter is calendered, the other not. There are alſo mohairs both plain and watered, whoſe woof is of wool, cotton, or thread.

MOHAIR-*Shell*, in *Natural Hiſtory*. See MOIRE.

MOHANG-LENG, in *Geography*, a town of the kingdom of Laos, ſo called by the Chineſe; *Mohang*, in the language of the country, ſignifying town. It is of conſiderable extent, but only encloſed with a paliſade; on the weſt are large foreſts and ſeveral rivers. This city ſtands on both ſides of a river, called Meinam Tai, which, by the Chineſe accounts, joins the river of Siam. Fiſh is rare, but buffalo and veniſon are common in the markets.

MOHANOO, a town of Hindooſtan, in the circar of Chanderee; 33 miles W. of Chanderee.

MOHASSIL, formerly called "Difterdar," an officer at Aleppo, is reckoned the ſecond perſon of the city in the civil line, and, on the demiſe of the baſhaw, is by the Divan uſually appointed Mutſillem, or temporary governor, till orders come from the Porte. He is farmer-general of the land-tax, the cuſtoms, and the capitation tax; on which account he is obliged to retain a number of ſubordinate officers diſperſed in the province, and to perform conſiderable buſineſs. He exerciſes a limited judicial power in matters of revenue, and has a priſon in his own palace. The Mohaſſil's influence is conſiderable: he lives ſplendidly, and is much courted by the agas or land-renters, as well as by the merchants. He is, from his office, one of the members of the Divan, or council.

MOHAUN, a town of Hindooſtan, in Oude; 15 miles N. of Lucknow.

MOHAWK BAY, a bay in Frederickſburg, Upper Canada, which lies oppoſite to Mohawk's ſettlement, and cloſe to the mouth of the river Apannac.

MOHAWK *River*, a river of New York, which riſes to the northward of Fort Stanwix, about eight miles from Black or Sable river, a water of lake Ontario, and runs ſouthwardly 20 miles to the fort, then eaſtward 110 miles, and after receiving many tributary ſtreams, falls into Hudſon's river, by three mouths, oppoſite to Lonſinburgh and Troy, from ſeven to ten miles N. of Albany. This fine river is navigable for boats from Schenectady, nearly or quite to its ſource; and the opening of this navigation by means of the locks and canals round the Little Falls, completed in 1795, is very advantageous to the commerce of the ſtate. A ſhore of at leaſt 1000 miles in length is thus waſhed by boatable waters, excluſive of all the great lakes; and many millions of acres of excellent tillage land, rapidly ſettling, are accommodated with water communications for conveying their produce to market. The intervals on both ſides of this river, of various widths, are ſome of the richeſt and beſt lands in the world; and are diſtributed into farms, which are occupied and cultivated principally by Dutch people, whoſe agricultural practice admits of great improvement, as they neglect to employ the manure of their barns in the culture of their land. The banks of this river were formerly thickly ſettled with Indians; and at the period when Albany was firſt ſettled, it is ſaid that at Schenectady there were 800 warriors, and that 300 warriors ſubſiſted within a ſpace now occupied by a ſingle farm. About three miles from

from its entrance into the Hudson, the river is about 1000 feet wide; the rock over which it pours, as over a mill-dam, extends from S.W. to N.E. almost in a line from one side of the river to the other, and is about 40 feet in perpendicular height, and including the descent above, the fall is as much as 60 or 70 feet. About a mile below the falls is a handsome bridge; and immediately below the bridge the river divides into three branches, which form several large islands.

MOHAWK, or *Cookquago*, a branch of Delaware river, which, after it mingles with the Popachton branch, is called Delaware.

MOHAWK, formerly a town on the S. side of the river of the same name, in Montgomery county, New York, situated in a very fertile country. It was abandoned by the Mohawk Indians in 1780.

MOHAWKS, an Indian nation, acknowledged by the other tribes of the Six Nations to be the true old heads of the confederacy. They were formerly very powerful, and had their habitation on Mohawk river. As they were strongly attached to the Johnson family, a part of them emigrated to Canada with sir John Johnson as early as the year 1776. About 300 of this nation now reside in Upper Canada.

MOHAWK *Settlement* is in the bay of Quinti, Upper Canada, W. of Richmond, and comprehended between the river Shannon and Bowen's creek.

MOHAWK *Village*, on the Grand river, or Ouse, in Upper Canada, is the principal village of the Six Nations, in the tract purchased from the Missassaga nation, by his present majesty, on account of their loyalty and attachment during the late revolution, in which they lost their possessions on the Mohawk river. This tract is 100 miles long, and 12 wide, intersected by Grand river, from its mouth in lake Erie upwards. The village is beautifully situated, has a neat church with a steeple, a school-house, and a council-house; and not far from it a grist and a saw-mill. These buildings have for the most part been erected by government, which pays a miller, schoolmaster, and blacksmith, for their services at the village; and the society for propagating the gospel makes an allowance to a clergyman of the established church for occasional visits to these tribes. The liturgy of the church of England has been translated into the Mohawk language, and printed for the use of the Six Nation Indians. In 1800, this nation, the Seneca and Oneida pagans, revived their custom of sacrificing white dogs to their gods, which had been neglected for 30 years, under a notion that the neglect of this sacrifice had been one cause of their various misfortunes.

MOHAWKS' *Corn*, in *Botany*, a name given by the Indians to a peculiar sort of the maize, or Indian corn. It is most frequent in the more northerly parts of America. The general time of sowing the maize in Virginia and other places, is in the end of April; but this mohawk kind need not be sown before June, and yet will come well to maturity before the winter. The stalks of this kind are shorter than those of the common sort. The ears also are shorter and grow nearer the ground, and the corn is generally of various colours. Phil. Transf. N° 142.

MOHAWK. See MOCK.

MOHAWRY, in *Geography*, a town of Hindoostan, in the circar of Chanderee; 45 miles W. of Chanderee.

MOHEGAN, a place situated between Norwich and New London, in Connecticut, in America; which is the residence of the remaining few of the Mohegan tribe of Indians. A considerable part of this small number removed lately to Oneida, with the late Mr. Occom.

MOHELNO, a town of Moravia, in the circle of Znaym; 24 miles N. of Znaym.

MOHERNANDO, a town of Spain, in New Castile; 10 miles N. of Guadalajara.

MOHERRY, a town of Hindoostan, in the circar of Cicacole; 20 miles S.W. of Ganjam.

MOHGONG, a town of Hindoostan, in the circar of Ruttunpour; 16 miles S.E. of Dumdah.

MOHICCONS, a tribe of Indians, whose habitations lie on a branch of the Susquehannah, between Chagnet and Gwegy. Hutchins, some years ago, reckoned them at 100, but Imlay, in 1773, estimates them only at 70 fighting men. They were formerly a confederate tribe of the Delawares.—Also, an Indian tribe, in the N.W. territory, which inhabits near Sandusky, and between the Scioto and Muskingum: their warriors are reckoned to be 60.

MOHILA, one of the Comora islands, in the Indian sea, between the island of Madagascar and the coast of Africa. It has a good road for ships, and it is said to be fertile. It is governed by a sultan, whose children share his authority in different districts of the island, bear the same appellation, and possess the same insignia of state, though they hold their power in subordination to him. The sultan himself never appears in public, without being attended by 20 of the principal persons of the island, and on such occasion his dress is a long robe of striped calico, hanging from his shoulders to his feet, with a turban on his head. The people are also generally clad in the same manner, and are perpetually chewing the areca, or betle nut, like the Indians of the East, whose manners they greatly resemble. S. lat. 12° 30′. E. long. 43° 50′.

MOHILL, a post-town of the county of Leitrim, Ireland; 78 miles W.N.W. from Dublin.

MOHILNA, a town of Poland, in Volhynia; 44 miles N. of Zytomiers.

MOHILOW, a town of Poland, in the palatinate of Braclaw; 60 miles S.W. of Braclaw.

MOHN, called by the Esthonians "Muhoma," which literally signifies the land of boils or sores, an island of the Baltic, separated from the main land by a strait, called the Great Sound, about two Swedish miles over in its broadest part, and near a mile where it is narrowest; the transport being made in summer by large boats, called Prames. Boats of a similar kind pass between Mohn and Oesel, across the Little Sound, which bears some resemblance to a spacious haven. Mohn lies to the S.W. of Oesel, forming a parish of itself, with its own church and preacher. Near the middle of the island, on an eminence, stands the church. Many of the boors live here comfortably; and having a little portion of forest, which, and also their hay fields, are inclosed by a wall of stones. As a shelter from storms, to which these seas are subject, some have their houses built in the midst of these little thickets. Not only acorns and bilberries, but also wild nuts and crab apples grow here, of which last the boors make a tolerably well tasted cyder; and in the farms they use them also for swine-wash. The circumference of the whole island measures about 95 versts. The passage over the Great Sound in summer is made with oars in about four hours, but with a sail and fair wind in less than two. To Mohn belong two small islands; one lying towards the N., and quite uninhabited, is merely a hay-field for the boors of Mohn; the other lies nearly between Oesel and Mohn in the Little Sound, and is occupied by three boors. On Mohn is a large stagnant lake, from which a canal has been made into the sea. Tooke's Russ. Emp. vol. i.

MOHO, a town of Peru, in the diocese of La Paz; 25 miles S.E. of Asungaro.

MOHR, a town of Germany, in the county of Hoya; five miles W. of Hoya.

MOHRAU, a town of Sileſia, in the principality of Neiſſe, near a river of the ſame name; 28 miles S. of Neiſſe.

MOHRIA, in *Botany*, a curious genus of ferns, named by Dr. Swartz after his friend Dr. D. M. H. Mohr, of Kiel, the coadjutor of profeſſor Weber, in ſeveral excellent botanical publications, particularly reſpecting the claſs *Cryptogamia*. In theſe he has diſplayed great knowledge and application, though not without ſome inaccuracy, and rudeneſs, rather than acrimony, of criticiſm. Experience, and a naturally good diſpoſition, would gradually have overcome ſuch defects, while his ſcientific abilities would have rendered the moſt extenſive ſervices to botany, had not an early death diſappointed the hopes of his friends.—Swartz. Syn. Fil. 6. 159.—Claſs and order, *Cryptogamia Filices*. Nat. Ord. *Filices*. Linn. Juſſ.

Gen. Ch. *Capſules* ſeſſile, diſtinct, roundiſh, depreſſed, concentrically ſtriated, of one cell, burſting by a longitudinal fiſſure at one ſide, without any ſeparate ring, ſituated near the margin of the frond. *Seeds* numerous, roundiſh, minute. *Involucrum* from the crenate inflexed margin of the lobes.

Eſſ. Ch. Capſules near the margin of the frond, diſtinct, ſeſſile, concentrically ſtriated, without a ring, burſting longitudinally. Involucrum from the crenate inflexed margin.

1. M. *thurifraga*. Incenſe-fern. Swartz. Syn. Fil. 159. 385. t. 5. (Polypodium caffrorum; Linn. Mant. 307. Adiantum caffrorum; 447. Oſmunda marginalis; Lamarck Dict. v. 4. 655. O. thurifera; Swartz in Schrad. Journ. for 1800. 105. Filicula æthiopica, denticulatis pinnulis, averſâ parte, Aſplenii ritu, villoſâ lanugine tectis, pediculo ſplendente nigro; Pluk. Mant. 77. t. 150. f. 3.)—Gathered by Koenig at the Cape of Good Hope; by Sonnerat, as well as Commerſon, in the iſle of Bourbon. The *roots* conſiſt of many long, branched, blackiſh, hairy fibres. *Fronds* in denſe tufts, near a ſpan high, bipinnate, denſely clothed beneath with imbricated, taper-pointed ſcales, as are alſo the *ſtalks* in ſome degree. *Leaflets* of the barren fronds roundiſh or ovate, ſharply pinnatifid; thoſe of the fertile fronds, which are conſiderably taller, ovate, obtuſe, deeply and bluntly lobed, their edges, or terminations of the lobes, inflexed over the *capſules*, which are each the ſize of the ſmalleſt pin's head, ranged in a ſimple row, at a little diſtance from the margin of the leaflet. There are generally two *capſules* under each ſegment of the leaflet. The ſmell of the recent fern is ſaid to reſemble that of incenſe, or gum benzoin; hence the French in the iſle of Bourbon term it *la feuille d'encens*.

We cannot trace the error of Dr. Swartz's citation of Lamarck. His miſquotation of Plukenet could not, on account of the confuſed arrangement of this author's book, be, without great care, avoided; but we truſt our correction is right.—This genus differs from *Oſmunda* in the ſtructure as well as ſituation of its capſules, and is unqueſtionably very diſtinct from that and all others.

MOHRIN, in *Geography*, a town of Brandenburg, in the New Mark; 20 miles N. of Cuſtrin. N. lat. 52° 54'. E. long. 14° 31'.

MOHRUNGEN, a town of Pruſſia, in the province of Oberland, ſituated on a lake of the ſame name, which almoſt ſurrounds it; 55 miles S.S.W. of Königſberg. N. lat. 53° 31'. E. long. 19° 51'.

MOHUN, a town of Hindooſtan, in the circar of Kitchwara; 10 miles S. of Budawar.—Alſo, a town of Hindooſtan, in Oude; 16 miles N E. of Cawnpour.

MOHUNGUR, a town of Hindooſtan, in the circar of Gohud; 18 miles S.W. of Narwa.

MOHUR, in *Commerce*, a coin in the Eaſt Indies. Gold mohurs, ſometimes called gold rupees, are ſtruck at the mint of Calcutta, as well as Sicca rupees, called ſilver rupees; 16 of the latter are, by regulation, to paſs for one of the former. The value of the gold mohurs has undergone conſiderable variations at different periods. At preſent the weight of the mohur is 13.28 maſſa, or 190,894 grains, and its fineneſs $23\frac{21}{22}$ carats, containing 189,462 grains of fine gold; and it is, therefore, worth 1*l.* 13*s.* $6\frac{1}{2}$*d.* ſterling. At Madras, the mohurs, or gold rupees of Bengal, occaſionally paſs for four ſtar pagodas. (See PAGODA.) At Bombay, the gold mohur paſſes in account for 15 rupees. In 1774 the coin, called the gold mohur, or gold rupee, was ordered to be made of the ſame weight as the ſilver rupee, and to be equal in fineneſs to a Venetian ſequin; ſo that the proportion of gold to ſilver in the Bombay coins was nearly as 15 to 1. Afterwards this proportion ceaſed; and gold, coined according to the regulation of 1774, exchanged for only 13 times its weight of ſilver. Accordingly, in order to remedy this, it was ſettled in 1800, that the mohur ſhould be of the ſame weight and fineneſs as the ſilver rupee; and that it ſhould paſs for 15 ſuch rupees.

The following TABLE ſhews the Aſſay, Weight, Contents, and Value of the Eaſt Indian Mohurs.

	Aſſay.		Weight.			Contents in pure Gold.	Value in Sterling.		
	car.	gr.	oz.	dwt.	gr.	Grains.	£	s.	d.
Mohur, or gold rupee of Shah Allum, 1770	1	$2\frac{3}{4}$	0	7	$22\frac{1}{4}$	186.8	1	13	$0\frac{3}{4}$

Kelly's Univ. Cambiſt.

MOHURBUNGE, a province of Hindooftan, S.W. of Bengal.

MOHYLNA, a town of Lithuania, in the palatinate of Minfk; 36 miles S.S.W. of Minfk.

MOIA, a town of Naples, in Principato Citra; 18 miles S.S.W. of Cangiano.

MOJABRA, a town of Africa, in Tripoli; 10 miles E. of Augela.

MOJAN, an ifland in the Baltic, belonging to Sweden. N. lat. 39° 22'. E. long. 18° 45'.

MOJARA, a town of South America, in the province of Tucuman; 18 miles N. of St. Salvador de Jugui.

MOIDENA, a town of Bengal; 20 miles S. of Kifhenagur.

MOIDORE, Moeda, or *Lifbonnine*, in *Commerce*, an old gold coin, ftruck and formerly current in Portugal.

The moidore and its divifions are reckoned by the *rees*; which fee.

The gold pieces coined in Portugal before the year 1722, are now, on account of the figuorage and the rife in the price of gold, 20 *per cent.* higher than their original value: thus, the old dobras, coined at 20,000 rees, are worth 24,000: the Lifbonnines or moidores, coined at 4000 rees, are worth 4800; and the halves and quarters in proportion; but few of thefe coins are now in circulation. The gold coins ftruck fince 1722, are the dobra, of 12,800 rees; the meia dobra, Joanefe, or Portugal piece, of 6400 rees; the half Joanefe of 3200; the dezefeis teftoons, of 1600; the quartinho, of 1200; the oito teftoons, of 800; the old crufado, of 400, now very fcarce, and the new crufado, of 480 rees.

The Affay, &c. of Portugal Coins, will appear in the following Table.

	Affay.		Weight.			Contents in pure Gold.	Value in Sterling.		
	car.	gr.	oz.	dwt.	gr.	Grains.	£	s.	d.
Dobraon of 24000 rees - - - -	Standard		1	14	12	759.	6	15	0
Meio dobraon of 12,000 rees - - -	Ditto		0	17	6	379.5	3	7	6
Dobra of 12,800 rees - - - -	Ditto		0	18	6	401.5	3	11	$0\frac{3}{4}$
Joanefe of 6400 rees - - - -	0	$0\frac{1}{4}$	0	9	$6\frac{1}{2}$	203.	1	15	$11\frac{1}{4}$
Half Joanefe of 3200 rees - - -	0	$0\frac{1}{4}$	0	4	15	101.5	0	17	$11\frac{1}{4}$
Moidore, or Lifbonnine (½, &c. in proportion)	Standard		0	6	22	152.2	1	6	$11\frac{1}{4}$
Piece of 16 teftoons, or 1600 rees - -	0	$0\frac{3}{8}$	0	2	6	49.3	0	8	$8\frac{1}{4}$
Piece of 12 teftoons, or 1200 rees - -	0	$0\frac{3}{8}$	0	1	$16\frac{1}{4}$	36.7	0	6	6
Piece of 8 teftoons - - - -	0	$0\frac{3}{8}$	0	1	$4\frac{1}{2}$	25.9	0	4	7
Old crufade of 400 rees - - -	0	$0\frac{1}{2}$	0	0	15	13.6	0	2	5
New crufade of 480 rees - - -	0	$0\frac{1}{3}$	0	0	$16\frac{1}{4}$	14.7	0	2	7
Milrea, coined for the African colonies, 1755	Standard		0	0	$19\frac{1}{4}$	18.1	0	3	$2\frac{1}{2}$

The impreffions on the gold coins of Portugal are as follows:

The dobraon: arms of Portugal, with 20,000 on one fide, and five flowers on the other: legend, JOANNES V. D. G. PORT. ET ALG. REX. (John V. by the grace of God king of Portugal and Algarves): reverfe a crofs, with four M's in the four angles; legend, IN HOC SIGNO VINCES, (by this fign thou fhalt conquer). The half dobraon bears the fame impreffions, except that it is marked 10,000.

The moidore bears the fame impreffions as the dobraon, except that it is marked 4000, and has four B's in the four angles of the crofs; but fome of an ancient date bear on the reverfe a crofs, furrounded by four connected femi-circles, and a whole circle, with the legend ET BRASILIÆ DOMINUS ANNO, &c. (and lord of Brazil, in the year, &c.) The half and quarter moidores are marked 2000 and 1000; their impreffions are in other refpects the fame as on the moidore.

The Joanefe: head of the reigning fovereign, with name and titles; thus JOANNES V. D. G. PORT. ET ALG. REX; or MARIA I. D G. PORT. ET ALG. REGINA, (Mary I. queen of Portugal and Algarves); and the pieces coined by the prince regent, fince 1804, bear his head, with JOANNES D. G. PORT. ET ALG. P. REGENS (John, prince regent, &c.): reverfe, arms of Portugal. The dobra or double Joanefe, the half, quarter, and eighth Joanefe, all bear the fame impreffions.

The quartinho: arms of Portugal, with 100, and the legend, MARIA, D. G. &c.: reverfe, a crofs, with four flowers, and the legend IN HOC SIGNO VINCES, as before.

The old crufade: head of the reigning king; reverfe, a crown; legend, JOAN, V. D. G. P. REX, as before.

The new crufade: name of the reigning fovereign, over it a crown; and under the name two palms, with 400 at the bottom; reverfe the crofs and legend, as in the quartinho.

The milrea: coined for the African colonies,—arms of Portugal, with 1000 on the fide, and the name and title as above: reverfe, a crofs and circles as in the old moidores; legend, ET DOMINUS AF. OR. ANNO, &c. that is, "Dominus Africæ orientalis" (lord of eaftern Africa). Kelly's Un. Cambift.

MOIETY, Medietas, the half of any thing.

MOIGOLSCHAR, in *Geography*, a cape of Ruffia, on the N.W. coaft of Nova Zembla. N. lat. 72° 40'. E. long. 52° 14'.

MOIKA, a river of Ruffia, which runs from the right of the Fontanka, not far below its departure from the Neva, and runs almoft parallel with it, into which it falls to the left of the Great Neva, clofe above its mouth.

MOILON, is a name given by the French to a kind of ftone, that forms the upper cruft, and lies round the free ftone in moft quarries. It is an excellent fubftance for forming the body of fluxes or foft enamel.

MOIMENTA DE BEIRA, in *Geography*, a town of Portugal, in the province of Beira; 13 miles S.W. of Caftel Rodrigo.

MOINE, Peter le, in *Biography*, was born at Chaumont, in Baſſigny, in 1602. He entered into the ſociety of the Jeſuits at ſeventeen, and continued to ſerve it by his labours and writings till his death, at Paris, in 1671. The principal work for which he is famous as a poet, is "Saint Louis, ou la Couronne reconquiſſe ſur les Infidelles," in eighteen books, which, for a time, ſtood high among the epic poems in the French language. It is ſaid to diſplay a vigorous imagination, and conſiderable powers of poetical expreſſion. Boileau, being called upon for an opinion of Le Moine, ſaid, "he had too much extravagance for his praiſe, and too much poetry for his cenſure." He was a conſiderable writer in proſe, in which his ſtyle and manner reſemble thoſe of verſe. His "Peintures Morales;" "Traitè de l'Hiſtoire;" "La Galerie des Femmes fortes," have conſiderable merit. Moreri.

Moine, Stephen le, a very learned French Proteſtant divine in the 17th century, was born at Caen, in Normandy, in the year 1624. Having laid in a good ſtock of elementary learning at his native place, he was ſent to Sedan, where he went through a courſe of divinity under the celebrated Du Moulin. From thence he went to Leyden to ſtudy the Oriental languages. Upon his return to France in 1650, he was appointed paſtor to the church of Geſoſſe. He afterwards removed to Rouen, where his zeal in maintaining Proteſtant principles expoſed him to the perſecution of the Catholics. In 1676 he left France, came over to England, and was honoured with the degree of doctor by the univerſity of Oxford. From hence he paſſed over to Holland, and obtained the profeſſorſhip of divinity at Leyden, which he occupied with much reputation during the reſt of his life. In the year 1685, he publiſhed a collection of curious Greek treatiſes, relating to eccleſiaſtical hiſtory, preceded by long *prolegomena;* it was entitled "Varia Sacra, ſeu Syllоge variorum Opuſculorum Græcorum ad rem eccleſiaſticam ſpectantium." He was author of many other curious and learned works. He died in 1689, in the 65th year of his age. Moreri.

Moine, John le, a French cardinal, who flouriſhed in the 13th and 14th centuries, and founded a college at Paris called after his name, was a native of Creſſy, in Ponthieu. He was educated at the univerſity of Paris, where he ſtudied divinity and the canon law, and was admitted to the degree of doctor. After various promotions in the church, he was raiſed to the purple, either by pope Celeſtine, or by Boniface VIII. By the laſt mentioned pontiff he was held in high eſteem, and appointed his legate in France, at the time of his conteſt with Philip the Fair. In this buſineſs the cardinal was ready to ſacrifice the intereſts of the ſovereign and of his country, that he might gratify the ambition of the court of Rome. He died at Avignon, in 1313, He was author of "A Commentary on the ſixth Book of the Decretals," which is ſaid to diſplay the knowledge and abilities of an able and profound canoniſt. It was printed at Paris in 1536, and at Venice in 1586. Moreri.

Moine, Abraham le, a French Proteſtant divine, who was born towards the cloſe of the 17th century, and became a refugee in England on account of his religion. He officiated as miniſter to a French church at London, and died in the year 1760. He is known chiefly by "A Treatiſe on Miracles," which was written in anſwer to Chubb, and which, on many accounts, was thought well of by the late learned Mr. Hugh Farmer. Subjoined to the treatiſe on miracles is a poſtcript, intended to vindicate the authority of the ancient fathers, in anſwer to what had been advanced by Dr. Middleton in his "Free Enquiry." Le Moine publiſhed alſo "A Sermon in Defence of Sacred Hiſtory, in Anſwer to Lord Bolingbroke," and ſome other ſermons. He alſo tranſlated into the French language biſhop Gibſon's "Paſtoral Letters;" "The Trial of the Witneſſes of the Reſurrection of Jeſus;" and "Diſcourſes on the Uſe and Intent of Propheſy," by biſhop Sherlock. Theſe tranſlations are accompanied with curious and intereſting diſſertations, by the tranſlator. Gen. Biog.

Moine, in *Geography*, a river of Louiſiana, which runs from the N.W. into the Miſſiſippi, in N. lat. 40° 5′. W. long. 91° 54′.

Moine, *La*, a bay on the S. coaſt of Newfoundland; 25 miles E. of Cape Ray.

MOINEAU, in *Fortification*, is a flat baſtion, raiſed before a curtain when it is too long, and the baſtions of the angles too remote to be able to defend one another.

Sometimes the moineau is joined to the curtain, and ſometimes it is divided from it by a moat. Here muſqueteers are placed, to fire each way.

MOINHO Diego, in *Geography*, a town of Portugal, in Eſtramadura; 30 miles N.E. of Liſbon.

MOJOS, a town of South America, and capital of a province, in the viceroyalty of Buenos Ayres; 14 miles N. of St. Salvador de Jujui.

MOIRA, a poſt-town of the county of Down, Ireland, chiefly inhabited by perſons concerned in the linen manufacture, for which the neighbouring country is peculiarly favourable. White lime-ſtone is abundant in the neighbourhood. Moira gives the title of earl to the Rawdon family. It is 69 miles N. from Dublin.

Moira's *Strait*, an inlet on the E. coaſt of the Prince of Wales's Archipelago, in the duke of Clarence's ſtrait. N. lat. of the entrance 54° 58′. E. long. 228° 22′.

MOIRANS, a town of France, in the department of the Jura, and chief place of a canton, in the diſtrict of St. Claude. The place contains 1190, and the canton 6855 inhabitants, on a territory of 195 kiliometres, in 30 communes.

MOIRE, in *Conchology*, the mohair ſhell, a name given by the French virtuoſi to a peculiar ſpecies of *voluta*, which ſeems of a cloſely and finely reticulated texture: and reſembles on the ſurface a piece of mohair, or a very cloſe ſilk-worm's web.

MOISDON la Riviere, in *Geography*, a town of France, in the department of the Lower Loire, and chief place of a canton, in the diſtrict of Chateau-Briant; ſix miles S. of it. The place contains 1505, and the canton 4958 inhabitants, on a territory of $257\frac{1}{2}$ kiliometres, in 5 communes.

MOISIE, a river of Lower Canada, on the N. ſhore of the St. Lawrence, a little E. of the Seven Iſlands: it runs into the latter river in N. lat 50° 15′. W. long. 65° 40′.

MOISSAC, a town of France, in the department of the Lot, and chief place of a canton, in the diſtrict of Montauban, ſituated on the Tarn, near its confluence with the Garonne; 13 miles N.W. of Montauban. The place contains 10,035, and the canton 14,008 inhabitants, on a territory of $162\frac{1}{2}$ kiliometres, in ſix communes. N. lat. 44° 6′. E. long. 1° 10′.

MOISTURE. See Humidity and Hygrometry.

The inſtrument uſed for determining the degree of moiſture in the air is called an hygrometer. Under the article Hygrometry, we forgot to introduce an account of a new hygrometer, with which the editor was ſome years ago favoured by Mr. Coventry, of Southwark, the conſtruction of which is as follows: take two ſheets of fine tiſſue paper, ſuch as is uſed by hatters and watch-makers, and ſometimes called lawn-paper, each ſheet of which generally weighs about twenty-ſeven grains. Let the moiſture be thoroughly evaporated by the fire, without scorching the paper; till after repeated trials it is brought to its driest state: in this state cut each sheet till it weighs exactly twenty-five grains. These sheets, thus prepared, should be kept in a box or drawer, with a quantity of the same paper designed for use; and they will always serve for determining the proper weight of any quantity of paper for other hygrometers. This paper hung in any place, and kept free from dust, and weighed with a nice pair of scales, will serve to exhibit the moisture of the air, by its increase of weight above fifty grains. But to avoid the trouble of weighing, Mr. Coventry prepared an hygrometer of it in the following manner. A (*Plate* XIV., *Hydraulics*, *fig.* 2.) represents a pillar supporting the beam B B, to one end of which are suspended fifty grains of paper D, cut round, and threaded on a silk string, with a small glass bead between the sheets, for the freer admission of the air: at the other end of the beam is a brass weight E, to counter-balance the weight of the paper and its appendages. At the bottom there is an ivory scale F F, of twelve prime divisions, answering to twelve grains of moisture: each prime division is subdivided into ten parts, making in the whole 120 divisions: on the index C is a sliding weight G, which, with the weight E on the beam, serves to adjust the instrument; so that twelve grains shall make the index just traverse the scale of the twelve divisions. If the air was so dry as to leave no moisture in the paper, the index would then point to 0: if it contained six grains of moisture, the index would point to sixty; if twelve grains were in the paper, it would point to the moist extreme, one hundred and twenty: but the air has never yet been observed so moist, as to make the index point to the moist extreme, nor so dry as to allow its reaching to the driest extreme, even in the hottest part of summer, by nearly twenty divisions: whence it is inferred that there is in the air a greater quantity of moisture in hot weather than is generally imagined. H is an adjusting screw for fixing the stand upright by means of the point of a plummet that hangs behind. This hygrometer, adjusted, may be made to correspond with another, ascertained to the same weight at any distance: by which we might determine the exact difference of the state of the air, with respect to moisture, in inland, and places near the sea-side. The advantages of this hygrometer are the following: as it is made of the thinnest substance that can be procured, it is the soonest affected with dryness or moisture, and exhibits immediately the first change of the weather: it is not acted upon by heat or cold, or any other cause, as most other instruments of this kind are; it has one datum from which to reckon, *viz.* the dry extreme, whence all other degrees of moisture may be nicely estimated. All hygrometers of this sort will act nearly alike, as thermometers or barometers; and may be reduced to a regular standard. Mr. Coventry found by this hygrometer, that in clear frosty weather, the air contains a very considerable degree of moisture: for on Jan. 27, 1776, in the morning, being a very hard frost, the thermometer in the house 24°, and in the open air 17°, the hygrometer stood at ten grains, *i. e.* at the division 100: and on the next morning, when a thaw came on, it stood at 96; which shews that there is as much moisture in the air during the frost, as when we perceive it dissolved in a thaw. He adds, that it is pleasing to observe the constant motion of this hygrometer: for even in constant settled weather, it is always in motion, from moist towards dry, from about eight in the morning till about four in the afternoon: and from dry to moist, from about 4 P.M. to about 8 A.M. In hot gloomy weather, the hygrometer is mostly found to advance with speed towards moist, and shews that the air at such times retains a great quantity of moisture: and this always forebodes heavy showers. For curious experiments some of these hygrometers are made to traverse the whole scale of divisions for every grain of moisture that is imbibed by the papers.

MOISTURE, *Radical.* See RADICAL.

MOITORET, DE BLAINVILLE, ANTHONY, in *Biography*, a French architect and geometrician, was born at a village four leagues from Dijon, in the year 1650. His genius led him to the study of geometry and architecture, in which he became an expert proficient, and settled in business at Rouen. Here he acquired considerable reputation by his skill as an artist, and by his useful and popular elementary writings. He was appointed surveyor and guager-royal of Rouen, under which office the public breweries of that city were included by a commission from the king. He died at Rouen in 1710, when he was about sixty years of age: he was author of "A Treatise on Guaging, with Instructions for measuring Mason's Work, &c." which went through several editions during the author's life, and after his death it was republished with improvements at Rouen, in 1714, under the care of M. Hacquet, with the title of "Blainville's New Elements of Geometry." He also published "A Treatise on the extensive Commerce of France, for the Information of Tradesmen," which was reprinted after his death, in 1728, with considerable additions, in two volumes: he is author, likewise, of abridgments "On the Art of Levelling;" "On Spherics," &c. which were favourably received by the public, and became very popular.

MOIVRE, ABRAHAM DE. See DE MOIVRE.

MOKA, in *Geography*, a town of Hindoostan, in Golconda; 28 miles S. of Adoni.

MOKAMO, a town of Hindoostan, in Bahar; 40 miles N.E. of Ramgur.

MOKATTAM, a mountain of Egypt, near *Cairo*; which see.

MOKEIA IBN AMER, a town of Arabia, in the province of Yemen; 22 miles N.N.E. of Chamir.

MOKERAMPOUR, a town of Bengal, 12 miles from Midnapour.

MOKESSET, a town of the Arabian Irak, on the Tigris; 116 miles N.W. of Bassora.

MOKEYA, a name given by the Arabs to those coffee-houses which stand in the open country, and are intended, like our inns, for the accommodation of travellers. They are mere huts, and are scarcely furnished with a "serir," or long seat of straw ropes; nor do they afford any refreshment but "kischer," a hot infusion of coffee-beans. This drink is served out in coarse earthen cups; but persons of distinction always carry porcelain cups in their baggage. Fresh water is distributed *gratis*. The master of the coffee-house lives commonly in some neighbouring village, whence he comes every day to wait for passengers. We may here observe that a "mansale" is a house in which travellers are received and entertained *gratis*, if they content themselves with such treatment as is usual in the country; they are all lodged in a common apartment, which is furnished with a "serir," and are served with "kischer," hot millet bread, camels' milk, and butter. Niebuhr.

MOKLAFF, in *Geography*, a town of Arabia, in the province of Yemen, the residence of a scheick; 30 miles S.E. of Loheia.

MOKLIA, or MUCHLI, a town of European Turkey, in the Morea; 16 miles S.S.W. of Argos.

MOKNAN, or MOHANAN, a town of Egypt, on the W. side of the Nile, near which, according to Dr. Pocock and M. d'Anville, was the scite of the ancient Memphis; 5 miles S. of Gizeh. See MEMPHIS.

MOKO, a town and diſtrict of Africa, in the country of Calabar.

MOKOKF, in *Botany*, Kæmpf. Amœn. 873. t. 774, a Japaneſe tree, with very fragrant but ſhort-lived bloſſoms, the *Cleyera japonica* of Thunb. Jap. 224. This proves of the ſame genus with the Linnæan *Ternſtroemia*, and the *Taonabo* of Aublet. (See TERNSTROEMIA.) Some diſcordance between the deſcriptions of Kæmpfer and Thunberg, which puzzled Juſſieu, aroſe from a degree of inaccuracy in Thunberg's deſcription of the corolla, which is really monopetalous, like that of *Camellia*.

MOKOMOE, in *Geography*, a town of Bengal; 37 miles N.E. of Ramgur.

MOKONTPOUR, a town of Hindooſtan, in Oude; 14 miles S. of Canouge.

MOKRETZ, a town of European Turkey, in Bulgaria; 44 miles S.S.E. of Viddin.

MOKSCHAK, a town of Ruſſia, in the government of Penza, near the ſource of the river Mokſcha; 36 miles W.N.W. of Penza. N. lat. 58° 40′. E. long. 44° 50′.

MOKUI, a town of Mingrelia; 20 miles N.E. of Iſgaur.

MOL, Fr. an epithet which Ariſtoxenus and Ptolemy give to a kind of diatonic genus, and a ſpecies of the chromatic. See GENUS.

For modern muſic the word *mol* is only uſed in compoſitions where B ♭ occurs, or B *mol*, in oppoſition to B-*quarre*, or B-*quadro*, which formerly was called B-*dur*, or B-*durum*. Zarlino, however, calls the diatonic mol a kind of diatonic genus. See DIATONIC.

MOLA, PIETRO FRANCESCO, in *Biography*, was a celebrated painter, born at Lugano in 1609. He was a diſciple of Ceſari d'Arpino, but did not follow the principles of that maſter long, having too good a taſte not to improve by an abode which he enjoyed for ſome time at Venice, where he carefully ſtudied the works of Titian. Mola poſſeſſed conſiderable ſkill in hiſtorical painting; but his forte lay in landſcape; the heroic ſtyle of which he ſought from Titian; but, like him, he often weakened the intereſt of his pictures by the introduction of figures upon ſo conſiderable a ſcale as to excite a doubt which is principal, the actors or the ſcene. His peculiar excellence lay in the richneſs of his colour and the freedom and fulneſs of his touch; together with the grandeur of compoſition which he exhibited in his landſcapes, frequently not unworthy of Titian himſelf. There is a picture by him in the gallery of the Louvre in Paris, which for ſublimity almoſt vies with the St. Peter Martyr; and for colour, is quite equal to it. The ſubject of this picture is St. Bruno's Viſion in the Deſart.

The genuine pictures of this maſter are rarely to be met with in this country, though there is plenty of thoſe which bear his name, and perhaps were executed by his brother Giovanni Battiſta Mola; whoſe works bear more reſemblance to Albani than thoſe of Franceſco. He died in 1665, at the age of 56.

MOLA, or *Mola di Gæta*, in *Geography*, a town of Naples, in the province of Lavora, ſituated near the ſea. It has a cuſtom-houſe and a garriſon, which is relieved every week from Gæta. It was anciently a Roman colony, but after the defeat of the Samnites it became a prefecture, and thus continued till it was ranked among the military colonies of Italy by the triumvirs Octavius, Antonius, and Lepidus. Under the emperors it became conſiderable; but it was at length ranſacked and deſtroyed by the Saracens in 956, and its biſhopric transferred to Gæta. It is ſituated on the ancient Appian way; and it was from this place that Cicero endeavoured to make his eſcape into Greece. (See CICERO.) The city of Formiæ ſtood on or near this ſpot. Between Mola and Gæta the road is rendered agreeable by the number of orange-trees which are planted in the adjoining fields; three miles N.E. of Gæta. N. lat. 41° 18′. E. long. 13° 29′.

MOLA *di Bari*, a town of Naples, in the province of Bari, on the coaſt of the Adriatic; 20 miles E. of Bari.

MOLA, in *Phyſiology*. See MOLE.

MOLA, in *Ichthyology*, a ſpecies of *Tetrodon*; which ſee: —Alſo, a ſpecies of *Diodon*; which ſee.

MOLA, in *Anatomy*, a bone of the knee, called alſo *patella*, *rotula*, &c.

MOLANAGUR, in *Geography*, a town of Hindooſtan, in Bahar; 21 miles E.S.E. of Saſeram. N. lat. 24° 50′. E. long. 84° 32′.

MOLANDS, a town of Norway; 12 miles N.N.E. of Chriſtianſand.

MOLANUS, JOHN, in *Biography*, was born at Liſle, in Flanders, in the year 1533. As his parents were originally of Louvain, whither they returned with him while he was very young, and alſo on account of his having ſpent the greateſt part of his life in this city, the ſurname of *Lovanienſis* is generally given to him. He was educated at Louvain, where, having ſeduouſly applied himſelf to the ſtudy of divinity, he was admitted in the year 1570 to the degree of doctor of divinity, and for ſome years filled the chair of profeſſor of that faculty with great reputation. He was nominated cenſor of books by the pope and the king of Spain, as well as canon of the church of St. Peter at Louvain. He died in 1585, at the age of fifty-two. He was author of a great number of works which were in high eſtimation at the time when they were written, but are now ſcarcely ever enquired for. He was concerned, with other members of the univerſity, in publiſhing the Antwerp edition of the works of St. Auguſtine in the year 1577, and the notes at the end of the Latin bible of the divines of Louvain, publiſhed alſo at Antwerp in 1580. Moreri.

MOLANUS, GERARD-WALTER, a Lutheran divine and profeſſor in the ſeventeenth and eighteenth centuries, was born at Hamelen, in the duchy of Brunſwick-Lunenberg, in the year 1633. In 1660, he was elected profeſſor of mathematics, and in 1672 he became profeſſor of divinity in the *Gymnaſium* of Rintelen, in the duchy of Schaumburg. He obtained other inſtances of preferment, and took precedency in the ſtates of Calenberg, and was preſident of the conſiſtory of Hanover. He died in 1722, at the age of eighty-nine. He had collected a valuable cabinet of medals, and an excellent library, of which he made a good uſe. As an author his moſt important work was publiſhed firſt in the German language, in the year 1697, aud afterwards repeatedly reprinted in Latin, under the title of "Lipſanographia, ſeu Theſaurus Reliquiarum Electoralis Brunſwico-Luneburgicus." He was author alſo of "Epiſtola ad Dominum Joachimum Meyerum quâ exponit cogitationes ſuas de nummo aureo Poſthumi ab eo edito, &c." Moreri.

MOLAPARA, in *Geography*, a town of Bengal; 30 miles W. of Dacca.

MOLARES, in *Anatomy*, the grinding teeth. In the old arrangement, the five poſterior teeth on each ſide of the jaw are ſo called. At preſent the two front and ſmaller of theſe are called bicuſpides, and the term molares is applied excluſively to the three poſterior ones. See the deſcription of the teeth in the article CRANIUM.

MOLARIS *Glandula*, one of the mucous glands of the mouth, placed near the back grinding teeth.

MOLARES, in the *Natural Hiſtory of the Ancients*, the name for

for the compound mineral bodies we now call pyritæ, and marcasites.

MOLASSES. See Molosses.

MOLBETZKOI, in *Geography*, a town of Russia, in the government of Novgorod; 24 miles S.E. of Tichvin.

MOLCHINA, a town of Russia, in the government of Tobolsk; 60 miles S.E. of Narim.

MOLCZAR, a town of Lithuania, in the palatinate of Novogrodek; 16 miles S. of Novogrodek.

MOLD, or Mould, a market-town in the hundred of Mold, Flintshire, North Wales, is pleasantly situated in a small but fertile plain, surrounded by lofty and rugged hills. It consists chiefly of one long and very spacious street, and, according to the parliamentary returns of 1801, contains a population of 4235 persons. The market is held on Saturday every week, and there are four fairs during the year. The assizes for the county of Flint are holden in this town. On the north side of it rises a large mount called Baily-hill, said to be partly natural and partly artificial, the summit of which was formerly crowned by a Norman castle, probably erected by Eustace de Cruer in the reign of William Rufus. This fortress seems to have been a place of great strength, as the sides of the mount are not only very arduous of ascent, but are defended by a deep foss and ramparts. History records that it stood several sieges without being compelled to surrender, till at last it was stormed by the Welsh forces under the command of prince Owen Gwynedd, in the time of Henry I. Subsequent to this period it suffered many vicissitudes, and was completely demolished during the desperate contests maintained against England by the celebrated Owen Glyndwr. Wynne, in his History of Wales, informs us, however, that it was soon rebuilt, and thereafter once more levelled with the ground by Griffith a Gwynwyn, about the year 1267, since which time it does not appear to have been restored. The view from the scite of this castle, though circumscribed, is extremely beautiful. The church here is a very handsome edifice in the pointed style, consisting of a nave and two side aisles, with a tower at the west end. In the interior are several monuments. The living is a vicarage in the patronage of the bishop of St. Asaph. A considerable cotton-thread manufactory is carried on here. The vicinity of Mold is decorated by several mansions, some of ancient and some of modern erection, the seats of independent gentlemen, who generally reside on their estates. Of these the most conspicuous are Leeswood, Tower, Rhual, and Nerquis-hall. Immediately adjoining to Rhual is Maes-y-Garmon, or the field of Germanus, so called from its having been the scene of a most decisive victory achieved by the British Christians under the missionary bishops, Germanus and Lupus, over the Pagan Picts and Scots, in the year 448. A pyramidal stone, erected on the spot in 1736, by Nathaniel Griffith, the then proprietor of Rhual, bears a Latin inscription commemorative of the event. The hills which inclose the vale in which Mold is situated abound with rich lead mines some of which are wrought with signal advantage both to the proprietors and contractors. On Meel-y-Famma, the highest point of these hills, a monument has been lately erected by subscription, as a memorial of the event of our most gracious sovereign having reigned for the unusual period of fifty years. Beauties of England and Wales, vol. xvii. from Wynne's History of Wales.

Mold. See Mould.

MOLDAU, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 21 miles N.W. of Leitmeritz.

MOLDAVIA, a province of European Turkey, bounded N. and N.E. by Poland, from which it is separated by the Dniester, E. by Bessarabia, S. by Walachia, and W. by Transilvania; estimated at about 180 miles in its greatest length from N. to S., and somewhat less in breadth from E. to W. It is crossed from N. to S. by the river Pruth. Some lands in this province are very fertile, but a considerable part of the eastern division consists chiefly of deserts, and is uncultivated; and on the western side it is very mountainous. The Pruth and the Siret are its principal rivers. Its inhabitants are of Walachian extraction, and their religious profession is that of the Greek church; but they are intermixed by Mahometans, Russians, Poles, Rascians, and Armenians. About the close of the twelfth century a colony of Walachians from Transilvania settled in this country. They migrated under the conduct of a person named Bogdan, who established their government both civil and ecclesiastical; and who obtained, with a view to the latter, an archbishop and other ecclesiastics from the patriarch of Constantinople. As he was the first prince, and founded the chief towns, the country was denominated Bogdania. The prince or waywode of this province is styled hospodar, and is the vassal of the Ottoman Porte, to whom he pays a yearly tribute. Moldavia is divided into Upper and Lower. Upper Moldavia extends almost to Jassy, and its boundaries are the river Dneister on the E., on the N. that river and Poland, and on the W. Transilvania. Moldavia on the W. borders on the mountains of Transilvania; its southern boundary is the Danube; Bessarabia bounds it on the S.E., and on the E. it is bounded by the Dneister. Its capital is Jassy.

MOLDAVICA, in *Botany*, Tourn. Inst. 184. t. 85. Moldavian Balm. (See Dracocephalum.) Tournefort associates with it also the *Dracocephalum canariense* of Linnæus

MOLDAVITZA, in *Geography*, a town of European Turkey, in Moldavia; 40 miles W. of Suczava.

MOLE, Thomas, in *Biography*, a learned English Protestant dissenting minister, of whom little is known but from his works. He is supposed to have received his academical education under Mr. Jones of Tewkesbury, by whom bishop Butler, and archbishop Secker, were also inducted into the knowledge of the sciences and theology. He was probably first settled as minister at Uxbridge, in Middlesex, in 1725, from which place he removed in 1728 to Rotherhithe; and about the year 1743, he quitted Rotherhithe for Hackney, where he lived some years, and then returned to Uxbridge, or its neighbourhood, to spend the remainder of his life. The latter part of his days he employed in writing, in the Latin language, a life of the celebrated Laurentius Valla, including the religious and literary history of his time. The MS. of this work was sold at a common auction with his other books, and has probably been long since consumed as waste paper. Mr. Mole died near Uxbridge about the year 1780, at a very advanced age. He was the author of several single sermons and tracts, that do much credit to his talents as a writer and controversialist. Dr. Kippis ranks him, in point of learning, with Lardner, Benson, and Chandler; and Dr. Lardner has shewn his respect for Mr. Mole's critical skill, by incorporating with his own some very ingenious observations that he received from him, on the case of the demoniac who resided among the tombs on the coast of Gadara. Gen. Biog.

Mole, in *Agriculture*, is a small well-known subterraneous animal, which often does great mischief in the fields, by loosening the earth, raising hills, and destroying the roots of corn, grass, and other productions of the vegetable kind.

In respect to the natural history of the mole, as connected with

with the art of husbandry, it has been observed by M. Aurignac, that it lives under ground. Its health is liable to be injured by too free access of the air: yet that it sometimes leaves one subterraneous habitation and passes on the surface in search of a better. It lives on the roots of plants, on insects, and on worms. Hence it is commonly found in lands of soft fertile soil. It never fixes its abode in miry, nor in gravelly grounds. If surprised in its subterraneous recesses by water, it springs in great haste to the surface. And that in winter, and during rain, it betakes itself to the upper grounds, which are the least humid, and the least liable to be inundated. But in spring, the mole comes down from its winter residence to the meadows, where it finds a soft mould capable of being easily penetrated, and containing plenty of roots. And after suffering long drought, it flies to ditches, to the brink of the first stream, or to shelter under hedges. In the months of February, March, April, and May, the female produces its young; bringing commonly four or five at a birth. These animals prepare beforehand, for this occasion, an arched recess under ground in a situation somewhat elevated, and generally under cover of a bush or hedge. To the number of four or five mole-hills may be observed very near to the upper side of this recess. It cannot live without being at work. Being obliged to search under ground for its food, it forms there long tunnels or subterraneous passages, named in French *boyaux*. These tunnels are usually parallel to the surface of the earth, and vary in depth according to the changes of seasons, from four to six inches. And as the moles are almost equally afraid of cold and of heat, they make their passages the deepest, and work at the greatest distance under the surface, in summer and in winter. They are extremely timid when they perceive themselves to be in danger. They then penetrate by a perpendicular opening, to the depth of a foot and a half below the level of their ordinary residence. And in forming their passages they throw back the mould, which they remove towards the surface. It is thus the mole-hills are raised. Upon every new change of place a mole raises three, four, six, or even nine of these hills, according to its age. Consequently, all the mole-hills formed by any one mole, communicate by subterraneous passages with one another. When with any instrument, a tunnel or passage, recently formed by a mole is opened, the mole will, in a few minutes, come to close up the aperture, in order to secure herself from danger, and from the access of the external air. It constructs, for this purpose, over the aperture, an arch of loose mould, having, externally, the appearance of an oblong mole-hill, and mending up the tunnel much in the same manner in which a plumber might mend a leaden pipe, by clumsily applying, on the outside, a piece of lead to cover any hole in it. And should this new mole-hill likewise be broken down, the mole will again return to repair it. These two capital facts constitute the fundamental principles of the art of the mole-catcher. The mole works in all seasons; because it cannot otherwise have subsistence. That it sleeps, as some naturalists have affirmed, all winter, is not true. It is, however, languid in this season; working now much less than in summer. It is about the beginning of spring, that the mole sets to work with the greatest activity, and raises the greatest number of mole-hills. It is then obliged to find food for its young; as spring is its season for parturition. The ground is now more easily wrought than at other times. The animal, too, in itself becomes more vigorous, by the diminution of the cold, and the return of the genial temperature of spring. These are the causes of its increased activity in toil. The male is much stronger than the female, and raises a greater number of mole-hills, and those larger. The female works less than the male, throws up fewer mole-hills, and those smaller. And the young moles form only long covered ways at the surface; the mould raised over which is scarcely sufficient to hide them. When they begin to make mole-hills, these are small, without any regular shape, and arranged zig-zag. The hours of working, for moles, are at sun-rise, at the hour of nine in the morning, at noon, at three in the afternoon, and at sun-set. But it is at sun-rise, and at sun-setting, that they ply their work with the greatest briskness. And in times of drought, they do not throw up mole-hills, except at sun-setting. In winter their moments of working are when the earth is somewhat heated by gleams of sun-shine. The sense of seeing is exceedingly obtuse in the moles; but its hearing is exquisitely delicate and acute.

Mole-*Catcher*, a term applied to a person whose business is principally the catching and destruction of moles. See Mole.

Mole-*Catching*, the art of catching and clearing land of moles. It is stated in regard to the principles of destroying these animals, that it is difficult to take moles unless when they are at work. That the most favourable time for the mole-catcher is in the beginning of spring. And that it is in the meadows they should be, in this season, the most earnestly attacked. They are to be attacked at sun-rise, at the hour of nine in the morning, at noon, at three in the afternoon, or at sun-set. That it is better to commence an attack upon them at sun-rise, than at any other time in the day. And that the next most convenient hour is nine in the morning; because, if all the moles which are wished to be destroyed cannot be then taken, the operations may be renewed at those other hours in the day at which these animals are known to resume their work. In watching for a single mole, care must be taken to make no noise, and especially not to stamp nor beat upon the ground. One may, at any time, force a mole to come above ground, by pouring a sufficient quantity of water into its subterraneous recesses. And should a person happen to be near a mole-hill, when the mole happens to betray its presence by stirring the mould; let him then, with his hoe, break into the tunnelled passage between that and the next mole-hill; and let him, with a little earth, close up the passage at the aperture made with his hoe. The mole is now imprisoned between the mole-hill, and the place where its passage is broken into, and stopped up. If the earth of a mole-hill be freshed and newly raised, you may conclude that there is a mole within it. The same thing may be inferred of any number of fresh mole-hills within small distances of one another. Yet, however fresh the earth of any mole-hill, if there be in its centre a perpendicular hole of about two inches diameter; you may be sure that the mole is not within, but has left his residence in search of a better. And when you find an assemblage of mole-hills together, of which the earth is quite fresh; then, upon removing them all with the hoe, and laying open the passages communicating among them, you cannot fail to find the mole that works within. This labour might prove too tedious and troublesome. But it will become very simple, if the mole can be confined between two points not remote from each other. Nothing more will then remain to be done, but to open with the hoe the intermediate passage between these two points. And a mole may be reduced to confinement between two such points, by making a few slight openings in the length of the tunnelled passage, in which you desire to confine her. These openings interrupt her course; for she will not pass, till she shall have first repaired them. But when you break into the tunnelled passage of a mole, close the passage slightly with

with a little loose earth at both ends of the hole you have made.

It may be noticed, that in the practice of mole-catching on these principles, "the only instrument absolutely necessary to the mole-catcher is a hoe. But that it will be convenient that he have likewise at hand, a few pieces of straw, a few bits of paper, and a pitcher of water.

And thus prepared, "the first thing a mole-catcher should do on a farm or estate which he goes to free from moles, is to examine how those moles may be so confined, that he shall be able to attack them all at once; for by thus attacking them, he will the soonest accomplish his whole task."

In the plate of *Agriculture* (*Moles*), a representation is given of a meadow covered with mole-hills, as at *figs.* 1, 2, 3, 4, 5, 6, 7, which are taken from the work of a late French writer. And by surveying this meadow as a mole-catcher, he perceives a detached mole-hill, as *fig.* 1; and perceiving the earth composing it to be fresh, or newly thrown up, he concludes, then, that there is a mole beneath. The mole-hill is large; he thence knows the mole within it to be a male. And with respect to the two mole-hills, *fig.* 2, they are at no great distance one from another; of course he knows them to be the work of a single mole. They appear fresh; and he concludes the mole to be still busy within. They are small; he, on this account, supposes it to be a female that has made them.

And the three mole-hills, *fig.* 3, are near to one another; and, consequently, the work of a single mole. They are fresh; he of course knows the mole to be now at work within. They are large; and have therefore been thrown up by a male. The six mole-hills, *fig.* 4, are not distant from one another; they must have been all thrown up by one mole. They are fresh; the mole is still at work. They are small; and, therefore, raised by a female. The zig-zag covered ways, or imperfect mole-hills, as at *fig.* 5, are fresh; a young mole is beneath.

But the five mole-hills, as at *fig.* 6, are dry; they have been deserted. And the seven mole-hills at *fig.* 7. are yet fresh; but one of them, shewn at M, has a perpendicular hole opening at the top. The mole by which it was thrown up is hence known to be but just gone. By these observations he knows that there are in this meadow two male moles, two females, and a young one. And it is of consequence to know whether the moles be males or females, young or old. The males work quicker than the females; and are, therefore, to be more narrowly watched. The young ones, raising but a very little mould to cover them, as they move along at the surface, go also very quick; and should therefore be kept constantly in view, after they have once been discovered.

It may be observed, that in the operations for destroying them in the first case, as where a mole makes but one mole-hill, *fig.* 1, the mole-catcher removes this mole-hill with the hoe; and ascertains whether it has communication with any of the mole-hills adjacent. For this last purpose, he hems, or makes a slight noise, at the aperture or mouth of the internal passage from the demolished mole-hill. He at the same time applies his ear to listen what ensues within. If the mole-hill be without any communication with any other; the mole being nigh is frightened by the noise; he hears it stir; and it cannot escape him. With his hoe he lays open the tunnelled passage *a b*; and at *b* he finds the mole. But the creature, aware of its danger, may possibly have had time to descend deeper into the earth, by the perpendicular passage *b c*; he has then two methods for taking her; he either digs to *c*, and there finds his prey; or he pours in water at *b*, and the mole comes out of herself. On the other hand, if upon hemming he could not hear her stir; he concludes that this mole-hill communicates with others near it; and he proceeds in the following manner.

This is the second case, as that where a mole has thrown up two mole-hills A, B, *fig.* 2, he now makes an opening *d e*, more than nine inches long, in the direction of the tunnel which runs between the two mole-hills. With a little earth he closes the two ends *d*, *e*, of the tunnel. Within a few seconds, the mole, disagreeably affected by the air, and fearful of danger, comes to repair the breach, and is discovered by its working at *d*, or *e*. If it come to *d*, he knows that he shall find it between that point and the mole-hill A. And when it comes to *e*, he is sure of finding it between *e* and the mole-hill B. In either instance, he proceeds as was indicated in the first case; and lays open either that part of the tunnel which terminates at the mole-hill, or that which ends at B.

But in the third case, where the mole has thrown up three hillocks, C, D, E, *fig.* 3, he now makes the four apertures *f*, *g*, *h*, *i*. The mole will be soon discovered by its stirring the mould at *f*, at *g*, at *h*, or at *i*. If it work at *f*, it is confined between that point and the hillock C. If it be perceived to work at *i*, it is confined between the point *i*, and the hillock E. And if it work at *g*, or *h*, it is in the space between these two points.

And in these three suppositions, he operates as in the first case, by laying open that part of the passage within which the mole is confined. If the mole be shut up between *g* and *h*; and he does not choose to take the trouble of laying all that space open; he then removes the mole-hill D, and makes a third cut like the others. He watches for the working of the mole; and he then knows by the side this appears on, whether he shall find the animal between the third cut and the point *g*, or between that third cut and the point *h*.

Also in the fourth case, where a mole has made four or more mole-hills, *fig.* 4, he takes, for example, the six mole-hills F, G, H, I, K, L. He makes the cut *k l*. If the mole come to work at *k*, it is confined between that point and the mole-hill F. If, on the contrary, she come to *l*, she is confined between *l* and the mole-hill L. In either of these suppositions, he makes from K to F, or from *l* to L, the same means of operation as in the third case; that is, he proceeds just as if there were but three mole-hills.

But a different mode of operating in the second, third, and fourth cases, is this; he supposes, that when he has made the cut *d e*, *fig.* 2, the mole comes to work at *d*, and he observes it the moment it comes there. He knows that it must travel along *d e*, to repair the breach in its tunnel by an arch of earth, which it must raise from the bottom of the place laid open. If he remain there, without making a noise, he shall see it come to work. Then, to take this mole, he has only to put the end of his hoe behind it, before it comes to the point *e*. The earth which he had before put at the aperture, *d*, will hinder it to advance; the end of the hoe will prevent it from retiring; and he shall easily take it, by removing with his fingers that small portion of loose earth with which it is covered. Is it possible, even without an aperture, to know the moment a mole comes to work at it? Nothing more is, for this end, necessary, than to place there a chip of straw, bearing a bit of paper at its upper end. This small standard will be subverted, or at least shaken by the very first movement the mole shall make at the place where it stands. The shaking, or fall of the chip of straw, calls the mole-catcher to watch and take the animal within.

Also in the fifth case, where the mole comes not to work at at the cuts made firſt by the mole-catcher, he ſuppoſes, that if, after making the aperture *k l*, he finds that the mole continues to work at the mole-hill L; he is now ſure that it is between the point *l* and the mole-hill L, and his ſubſequent operations are the ſame as in the third caſe; that is, he muſt act as if there were but three mole-hills I, K, L.

In order to know whether a mole ſhall come during his abſence to work under a mole-hill, he ſoftly flattens the mole-hill with his foot; and if, on his return, he perceives a ſmall eminence to have been raiſed on the level, he can then have no doubt but the mole has been working there.

However, in the ſixth caſe, there is a different manner of operating from caſes ſecond, third, fourth, and fifth, where a perſon happens to be near a mole-hill at the moment when the mole breathes or blows at it. Should he be beſide the mole-hill L, *fig.* 4, at the moment when the mole comes to work there; he does not uſe the uncertain method of the gardeners, who remove the mole-hill with the ſpade; but he cuts at *m n*, the tunnel communicating between the mole-hill and the next one K. This is a certain means of confining the mole between the mole-hill and the point *m n*. When the mole is thus incloſed, he proceeds, as in the firſt caſe, and lays open the ſpace within which it is confined.

And in the ſeventh caſe, as when ſeveral freſh mole-hills are found near to ſome other mole-hills, old and dry, as *figs.* 4 and 6, which is more troubleſome than any other of the mole-catcher, it is doubtful whether the freſh mole-hills do or do not communicate by tunnels with the old and dry ones. It is neceſſary to begin by making cuts between the old and the new hillocks, that the mole, when attacked in the new, may not be able to eſcape to the old. One may then proceed, according to circumſtances, as in the foregoing caſes. When this happens to be the caſe, too many cuts cannot be made, unleſs a perſon is anxious to ſpare the ſurface of the ground. It is good, for inſtance, as in *figs.* 4 and 6, to make a cut in the direction from H to N, and another in the direction from H to O; as there may be a tunnel in either, or tunnels in both of theſe directions.

But on this, it is obſerved, that "if one were conſtantly to watch a ſingle mole, and not to proceed againſt any other, till after the firſt were taken; only a very few could be deſtroyed in one day. But when a farm is ſurveyed to diſcover the moles, all the freſh hillocks ſhould be greatly flattened with the foot, and all the neceſſary cuts made,—as of theſe too many cannot be made, unleſs a perſon is afraid of breaking the ſurface too much. Set up little ſtandards of ſtraw with paper ſtreamers. Then paſs about from one mole-hill to another, and proceed as directed above. If you thus proceed againſt ſeveral moles at once, you muſt exerciſe great vigilance; otherwiſe, while you are buſy with one mole, others may make a good paſſage acroſs the cuts; and then you will have to begin with them anew. A mole will be longer in repairing and croſſing one of the cuts, if a lump of hardened earth is put at the bottom. This precaution ſhould be always taken." This is conſidered by M. Dralet, the tranſlator of the above, as "of all the means hitherto employed for the extermination of moles, the eaſieſt and the ſureſt."

In the ſixth volume of the Agricultural Magazine, a writer, however, propoſes a more ſimple, eaſy, and effectual practice, and which is leſs troubleſome and expenſive. It is the invention of a common labourer, who clears nearly one half of the county of Glamorgan. His contrivance is compoſed entirely of oak, deal, or elm wood, but the firſt is the beſt, and common nails, and may be made by any carpenter or wheel-wright, and ſet to work by any common labourer. This is ſhewn at *fig.* 8, in the plate. A and B are two boards of oak, forming the ſides of the trap, eighteen inches long, five inches wide, and half an inch thick. C, the bottom of the trap, more fully explained in *fig.* 9. E, a piece of oak board, five inches long, two inches wide, half an inch thick, nailed on the top edges of the boards A and B, both to ſtrengthen the trap and to keep the ſides at a proper diſtance. A (*fig.* 9) is the trap with its bottom upwards. C, C, two pieces of oak board, five inches wide, four inches and a half long, half an inch thick. D, an aperture, nine inches long, four inches wide, made to receive the fall of the trap. L, a hole for a common clout-nail (forming the pivot of the fall) to turn in. And at *fig.* 10. is D, the fall of the trap, nine inches long from F to H, three quarters of an inch thick (the diſtance from F to G two inches and a half, or three inches), from G to H half an inch thick and four inches wide. G ſhews the hole for the clout-nail forming the pivot. M, the dotted lines, ſhews the manner in which the upper part of the fall D muſt be bevilled, to prevent its falling both ways. At *fig.* 11. is ſeen "the mole-pot, the uſes of which will be more fully explained afterwards, compoſed of four pieces of oak board, each five inches wide at the top, nine inches wide at the bottom, twelve inches long, one inch thick, or thereabouts, having two ears, as at K, K, with a hole in each large enough to carry a piece of ſmall rope or ſpun-yarn." And at *fig.* 12. is ſhewn a mole-trap ſet in the ſide of a ditch.

In the view of finding the runs or tunnels, "the farmer or his ſervant muſt carefully examine the ditches of each field, in order to diſcover where the moles have made their main tracks; which having once found, and the trap ſet thereon, he may reſt aſſured that every one paſſing through it will be inevitably deſtroyed; neither are their runs at all difficult to be found, as the only thing neceſſary to obſerve is, whereabouts they have broken out moſt on that part of the field the neareſt to the ditch, in the ſide of which he muſt then make an opening with a ſmall common ſpade, oppoſite to the neareſt place where they are obſerved to work moſt, in order to open the run. Should the firſt endeavour to ſtrike upon it prove unſucceſsful, he will not fail to find it by ſearching thereabouts, either a little higher or lower. In common fields and unincloſed lands a different method muſt be purſued; and as, of courſe, there are no ditches, the higher grounds and banks will be the certain and proper place to ſearch for their runs, which having once found, the workman muſt proceed in the following manner: Firſt, a hole muſt be cut out the length of the trap, as repreſented in *fig.* 12, in ſuch a manner that when it is inſerted, the run may enter each of its ends, as ſhewn by the dotted lines; and alſo a hole or well of ſuch a ſize that the mole-pot may be eaſily ſuſpended therein. Secondly, a ſmall clout-nail, of which he ſhould take ſeveral in his pocket; or ſhould he have forgotten to do ſo, a thorn out of the hedge muſt be thruſt into the hole *n*, *fig.* 9, which alſo communicates with the hole *n*, *fig.* 10, and will effectually prevent the fall from acting. Thirdly, a ſmall handful of fine earth, like that uſually thrown up by moles whilſt working, and which may be taken from one of their heaps, muſt be ſcattered all over the bottom of the trap ſo as to cover it, as well as both ends communicating with the run. Fourthly, a turf, ſomething longer and wider than the trap, muſt be cut off the head-land, both to ſerve as a cover to it, as is ſeen at P P P P, (*fig.* 12.), and as a certain mark by which it may be found with the greateſt eaſe: and laſtly, two pieces of ſpun-yarn muſt be faſtened, one to each ear of the mole-pot 11, *fig.* 4, by which it muſt be tied on the trap in ſuch a manner, that any weight put upon the fall D at 11 may be thrown to the bottom; the carpenter having previouſly taken care that the weight of the fall from F to G ſhall more than counterbalance that from G to H, ſo that no ſooner ſhall a mole be thrown into the pot than it will ſpontaneouſly reſume its former ſituation, and be on a level with the reſt of the bottom."

After "the trap with the fall has been faſtened up by the clout-nail at *n*, the fine earth ſtrewn over the bottom, the turf covered over the top, and the mole-pot properly ſuſpended, by being tied over the whole; nothing further will be required to be done to it for three or four days, (for the moles muſt be allowed to paſs freely along it for that time, as it will induce them to uſe their run without fear, and be the means of taking them with the greater certainty). The workman muſt now carefully examine his trap, and on gently lifting up the turf will plainly perceive their marks, (taking care, however, not to leave any opening for the light to enter), and pulling out the clout-nail at *n*, the trap will then be ſet fit for working, and the fall will throw them into the mole-pot, out of which it is impoſſible for them ever to eſcape." And farther, "ſhould the farmer have ſtrictly followed the above inſtructions, and notwithſtanding the moles ſtill continue to work about his land, he may be certain they have forſaken the run on which he has ſet his trap, and he muſt therefore ſearch for their new one." It is concluded that "the advantages ariſing from uſing traps of the above conſtruction are, that the materials are to be procured every where; they can be made by any common mechanic at a very ſmall expence, (the wood being uſed rough as it comes from the ſaw,) are very durable if made of oak; are not liable to get out of repair, and if they ſhould, can be mended moſt probably by a labourer; they catch the whole year, and do not require looking after more than three or four times in that period, and that will comparatively require ſo ſhort a time, that a workman may with eaſe look over all the traps on a very large farm; and ſuppoſing the fields to lie contiguous to each other, one trap for each ten acres would, on an average, be fully ſufficient."

It is ſtated, by the firſt writer noticed above, that mole-traps are either ſimple or complex. The ſimple mole-trap is a hollow cylinder of wood, white-iron, or pottery, thirteen or fourteen inches long, and in diameter a little larger than the tunnels of the mole. This cylinder is cloſed at one end, and has at the other a ſucker or valve preſſing againſt an exterior edging. When the mole comes to the extremity covered by the ſucker or valve, ſhe preſſes this back in order to continue her progreſs through the cylinder, and can return no more. Two of the traps may be united ſo as to form a double trap, having a valve at each end. By this the mole may be taken as ſhe enters, whatever ſide ſhe approach. It is added, that "the moſt remarkable of the complex traps uſed in Normandy, is a ſmall piece of board fixed in the ground by four iron pins with croſs points extending from them; and on theſe points the mole transfixes itſelf. It is very ſeldom that thoſe ſucceed who make uſe of theſe and other mole-traps: for they do not uſe the fit means to entice the creature to the ſnare. That method is, nevertheleſs, very ſimple. Nothing more is neceſſary than to make a few holes by which the air may enter the tunnel of the mole, and give her notice of the injury done to her work. It will be eaſy to him who has read the preceding information and directions, to employ ſuch mole-traps, in certain caſes, with infallible ſucceſs. He ſuppoſes, for inſtance, the two mole-hills A, B, (*fig.* 2.) and makes the aperture *d e*. If the mole ſtir the earth at *d*, he there preſents the valve of either the ſimple or the double mole-trap; and he is ſure of taking it. If, on the contrary, it preſents itſelf at *e*, he muſt there uſe the trap. He acts in the ſame way in every one of the caſes mentioned above. It may be eaſily believed, that there are ſome of thoſe caſes in which it will be convenient to uſe mole-traps. They are exceedingly uſeful when the mole-hills happen to be at conſiderable diſtances one from another, as in the end of winter. But, in the time of drought, and when the weather is very cold, the hillocks are ſo very near to one another, that the traps can be of little uſe.

But the common method of deſtroying moles is, however, by traps, made in the following manner: take a ſmall board, about three inches and a half broad and five inches long; on one ſide thereof raiſe two ſmall round hoops or arches, one at each end, like the two hoops or bails of a carrier's waggon, capacious enough for a mole to creep through eaſily: in the middle of the board make a hole about the bigneſs of a gooſe-quill, and have in readineſs to put into it a ſtick about two inches and a half long, fitted at one end to the hole and a little forked at the other. Cut alſo a hazel or other ſtick, about a yard or a yard and a half long, which will riſe with pretty ſtrong elaſticity when it is ſtuck into the ground; and to the end of this ſtick faſten a very ſtrong nooſe of ſtring or horſe-hair, made ſo as to ſlip eaſily. Have likewiſe in readineſs four ſmall hooked ſticks; then go to the furrow or paſſage of the mole, and after you have opened it fit in the little board with the bended hoops downward, ſo that when the mole paſſes that way it may go directly through the two ſemicircular hoops. But before you fix the board in this manner, put the hair ſtring through the hole in the middle of it; place the noose in a circular form, ſo as to make it anſwer to the two hoops; put the ſmall ſtick before mentioned gently into the hole in the middle of the board, ſo as juſt to ſtop the knot of the hair ſpring, without entering ſo far as abſolutely to tighten it. Then faſten the board down with four hooked ſticks, and cover it with earth. When the mole, paſſing in its furrow, comes into this trap, it will diſplace the ſmall ſtick that hangs perpendicularly downward, the knot will then be drawn through the hole, and the noose inſtantly ſtraightened by the riſing of the end of the hazel ſtick to which it is faſtened, will catch the mole round the neck or body and hold it faſt.

Moles, *Fumigating of.* This is a mode adopted in order "to ſuffocate the mole in its retreat, for which ſome adviſe to take a ſmall nut-ſhell, or any little vaſe, ſolid and of ſmall capacity, and in it to burn cedar root, or wax and ſulphur, with a portion of ſtraw, then to ſtop up every hole by which the ſmoke might iſſue out. The ſucceſs of theſe methods is very uncertain, and indeed none at all in the hands of any perſon not well acquainted with the artifices and haunts of the mole. Sometimes all the mole-hills in a garden or a meadow, whether freſh or dry, communicate by many different paſſages with one another, as has been ſhewn. In this caſe all theſe mole-hills muſt be preſſed down and cloſed up. But in doing this you will yourſelf preſerve the mole from the threatened ſuffocation. Suppoſe, for inſtance, that the mole which made the hillocks (*fig.* 4.) is to be ſuffocated, and that you put the combuſtible matters in at H. If the mole be at I or L, the ſmoke will be hindered from penetrating beyond I, by your ſhutting up the paſſage there; and your precaution to enſure the death of the mole will prove the very means of its eſcape. It is only by cuts in the paſſages that fumigation can be made effectual. To ſuffocate the mole of the hillocks (*fig.* 4.), make the breach *l k*: cloſe up its extremities; put in your combuſtible matters between *k* and F, and between *l* and L, after levelling the hillocks L, F. But you muſt firſt aſcertain whether the mole-

mole-hill, H, (*fig.* 4.) has any communication with thofe of *fig.* 6, and if it has, cut off that communication by other breaches," in the manner already defcribed.

There are fome other modes propofed for the deftruction of this animal, but they are much lefs certain than thofe which have been juft detailed.

Moles, *Poifoning of.* It may be noticed, that for this purpofe there are feveral recipes; fome propofe to throw into their retreats nuts, which have been pierced on one fide and boiled in a ftrong lixivium. Others boil fuch nuts in water, with a handful of hemlock, and ufe them as above. In fome countries people take the root of white hellebore, with the bark of dog's colewort pulverized and fifted; mix this with barley-meal: fteep the mixture in wine and milk; cut it in fmall pieces, then throw it into the mole-hills. In other countries it is ufual to take the green of a leek, or to put arfenic on the white, and bury this in the frefheft mole-hill that can be difcovered. Thefe poifons, it is obferved, are in general ufed injudicioufly. The mole rarely feeks its food at the furface where its hillocks are placed. It pufhes back the earth, as it works, to the extremity of its tunnel. That earth raifes the layer next above it; and by the continual repetition of this procefs, the mole-hill is at laft formed. The mole, while undifturbed, keeps always within its tunnel; and it is into the tunnel, therefore, that the poifoned bait ought always to be caft, inftead of being left in the hillock. In order to deftroy the mole which formed the mole-hills A, B, (*fig.* 2.) make a cut, *d e*, in the tunnel which communicates between them. Put the poifoned bait then into it, at either *d* or *e*, or even between them. The animal will come of courfe to repair the breach, will find the fubftance, eat it, and be deftroyed.

Mole-*Hill*, a term applied to a fmall mouldy heap of earth, thrown up by the mole on grafs or other lands. It has been obferved by a late writer, that "in the more rich and fertile foils, hills of this fort are frequently thrown up in great numbers, from their abounding more with the food of the fubterraneous animals that produce them. Meadows are often extenfively and ferioufly injured by them, on account of their depth of foft humid foil. Moles ufually refide, deftroy, and render ufelefs the grafs, not only of the very fpot where the hills are raifed, but likewife to fome extent immediately around them, as well as impeding the free courfe of the fcythe: for thefe reafons, the extermination of moles becomes an object of great confequence to grafs hufbandry. In the early fpring months, when fuch hills are in a tolerably dry and powdery ftate, no time fhould be loft in fpreading them out, and difperfing them, in as even and regular a manner as poffible, over the furface of the fward that adjoins them; as, when they remain long without being fcaled, they do confiderable injury to the grafs plants underneath them, by blanching and rendering them tender. This bufinefs may be very conveniently performed by a common iron-toothed garden rake. But it is invariably the beft method never to fuffer the animals to remain in the land, but to procure an expert mole-catcher to deftroy them, and thus wholly prevent the hills being thrown up." As foon as the hills have been difperfed over the land in the manner directed above, the operator fhould be careful in raking up all the fmall ftones, that may have been thrown out with the mould; as when left upon the ground, efpecially where it is to be mown, they prove a very difagreeable impediment to the fcythe. But before this is done, it is beneficial to make ufe of a bufh-harrow.

Mole-*Plough*, an implement intended for the purpofe of draining land, by forming a fort of pipe in it.

This plough was long ago invented by Mr. Adam Scott, and as fince improved, and made ufe of in the midland counties, is an implement which, in fuitable foils and fituations, as in parks, pleafure-grounds, and where much regard is had to the furface-appearance of the land, may be of confiderable benefit in forming temporary drains. It makes a drain, without opening the furface any more than merely for the paffage of a thin coulter, the mark of which foon difappears. This inftrument is chiefly employed in fuch grafs-lands as have a declination of furface, and where there are not many obftructions to contend with: but it may be ufed in other kinds of land, as on turnip grounds that are too wet for the fheep to feed them off, or where, on account of the wetnefs, the feed cannot be put into the earth. With this plough the drains fhould be made at the diftance of ten or fifteen feet, in ftraight lines, and alfo contrived fo as to difcharge themfelves into one large open furrow, or grip, at the bottom of the field. As it requires great ftrength to draw this implement, it can only be ufed where a good team is kept. It is fuggefted by an intelligent farmer, that in deep clayey foils it may be highly ufeful; but that, where there are beds of gravel or fand intervening, it cannot be employed with advantage. And it has been found ufeful in thin peaty foils.

This fort of plough is reprefented at *fig* 1, in *Plate Agriculture* (*Ploughs*), in which *a* is the beam; *b*, the coulter; and *c*, the cone which forms the drain. It has been lately improved, fo as to require much lefs force of draught, by having wheels placed before, and a roller behind. But a greater and more important improvement has been made on this tool by Mr. Lumbert. Mr. A. Young ftates, that "in a communication from his fon, inferted in the 36th volume of the Annals of Agriculture, mention is made of this plough having been greatly altered by Mr. Lumbert of Rilington Wick, near Stow, on the Wolds of Gloucefterfhire, who worked it by eight men turning windlaffes. This he takes to be the firft public notice of any fuch invention. Thomas Eftecourt, efq. M.P. for Cricklade, and a member of the Board of Agriculture, had, fince that period, feveral times mentioned the fame object to him. In March 1804, he had the goodnefs to inform him, that the plough was then working at Cricklade; and, upon his expreffing a wifh to fee it, obligingly propofed to write to Mr. Wells, furgeon at Cricklade, informing him of his intention, and requefting his writing to Mr. Lumbert, the inventor, to defire his prefence at the fame time. Thefe neceffary previous fteps being taken, he arrived at Cricklade, March 21ft, and had the fatisfaction to find that the plough was then at work within a mile of the town, whither he repaired with Mr. Wells and Mr. Lumbert. The field in which the machine was working belongs to Mr. Champernoun of Cricklade; the foil a very rich furface loam upon a clay bottom, which made it wet, and demanded the operation of draining. The ftate of the furface (though grafs) was fuch as would have been very materially injured, by fo many horfes as muft have been neceffary to draw the mole at the depth he found it working, which was from 17 to 18 inches. Eight women work it: and in refpect to the labour exerted, it is fufficient to note that Mr. Lumbert contracts for the work at three halfpence *per* perch, lug, or rod, of $5\frac{1}{2}$ yards; his foreman contracting with him for doing it at three farthings, the machine being found by the mafter, the man paying himfelf and the women out of that fum. The plough does, according to foil and circumftances, from 150 to 200 perches a-day: 300 have been done. At 200, three farthings a perch are 12*s.* 6*d.* *per diem*; the eight women at 8*d.* are 5*s.* 4*d.*; leaving

ing 7*s.* 2*d.* for the foreman's pay, and the reparation of the chain, the chief object in the repairs, as it breaks often, and wants the addition of a falſe link whenever that accident happens. He timed the motion of the plough for ſome rods, and found the average five yards in a minute. At this ſpeed, 490 perches would be done in nine hours; but the time of moving the windlaſs, frame, and anchor, is a large deduction, though he ſhould have conceived not ſufficient to reduce the performance to 200 perches. He could not but much admire the efficacy of the anchor and *ſcots*, in quickly fixing and preſerving the ſteadineſs of the machinery, in reſiſtance of ſo great a force as is neceſſary to move the mole deep buried in clay."

And it is added, that "the preſent conſtruction of the machine was the reſult of many experiments, in making them under divers variations. Mr. Lumbert ſpeaks of two circumſtances particularly, which coſt him much attention and many trials: the line of traction, and the due elevation of the beam. He has not comprehended why the beam ſhould be elevated (other circumſtances remaining the ſame); why any elevation further than parallel to the horizon ſhould be neceſſary, the parts connected forming one piece in either caſe. This queſtion, which is intimately connected with the ſtructure of all wheel-ploughs, and is found under great variations, from the elevated beam of the Norfolk plough to the very depreſſed poſition of the beam of the Hertford one, deſerves more attention than it has commonly met with. The line of ſurface being 1 : 2, and the tendency of the ſhare into the ground 1 : 3, ſhould the elevation of the beam be proportioned as 1 : 4? The line of traction, in Mr. Lumbert's plough, being to a little above 1, ſuppoſe his mole working at 5, he ſeems to have proportioned the elevation of his beam ſomewhat to the ſame angle above ground at 6, that is, at 22½ degrees. He found it neceſſary that the line of traction ſhould cut the centre of the front roller, but not drawing by it. If a line be drawn from the horſe's ſhoulder, while drawing, to the heel of the Norfolk plough, he has often found, when the ploughs *are ſaid* to go well, that ſuch line paſſes by the centre of the wheels; but the Norfolk plough is truly a wheel machine, the draught being to the carriage, and not to the plough itſelf: whereas Mr. Lumbert draws from the heel of his beam. The line of traction, however, in Mr. Lumbert's machine, is always varying: the angle is very acute, when the women begin to turn; but neceſſarily becomes leſs and leſs ſo, till the mole arrives at the windlaſs frame. The elevation of his beam throws a great weight on it, by counteracting the tendency of the mole into the ground. Quære, if this line of traction be not to the centre of the compound reſiſtance? If ſo, it explains the reaſon for his greater eaſe of draught; but it does not explain why he ſhould not have availed himſelf of high wheels in front, inſtead of a low roller, converting his machine into a true wheel-plough, and drawing from the carriage; the chain from the plough heel being fixed to the carriage, as that from the coulter (or near it) is in the common wheel-plough."

The ſame writer further ſtates, that "Mr. Lumbert has made this great improvement of the mole-plough about ſeven or eight years, and the ſucceſs attending it has been conſiderable. Mr. Poulton of Cricklade and Mr. Wells have uſed it, as well as Mr. Champernoun. Mr. Coxe at Water Eaton has drained, as he was informed, ſome hundreds of acres with it. Many have uſed it at Perton; nor had Mr. Adams heard of any failures. All known here have been on clay; but they have heard of its anſwering on leſs ſtiff bottoms. The drains run well after three years."

It is added, that "Mr. Lumbert, in their examination of the machine, deſired him to obſerve that the bottom of the mole was not at all bright, there being no wear there, while the upper parts were worn quite bright; and from this circumſtance he concludes, that any attention to keep froſts out of the ſlit made by the coulter and ſtandard is unneceſſary. He conceives that the force of preſſure, and conſequent plaſtering, is all on the upper ſide of the pipe, inſomuch that he is firmly perſuaded that the operation is chiefly at the bottom of the pipe, where the ſoil is left porous, on compariſon with the top of it: and he is ſo much of this opinion, that he conceives the water, which runs down by the ſlit, is more likely to be conducted over the pipe than to get into it." Mr. Young ſtates, that "he merely reports his remarks without a comment."

It is hinted, that "the improver goes to any part of the kingdom with his machine for draining of 1½*d. per* rod; but if to a diſtance, muſt have inſured work, in the proportion of 200 rods for every mile he travels going out. At any conſiderable diſtance, this amounts to ſo large a quantity, that, in many caſes, it would be adviſable for ſeveral neighbours to join for providing ſufficient employment. He ſells the tool complete at 50 guineas, having a patent. He can go 24 inches deep; and he has, on his own farm, drains that have ſtood well ſeven years. When the ditch of a field is not in ſuch a direction as ſuits for the conveyance of the water from the pipes made by the mole, or other circumſtances render it neceſſary to have a bottom main drain to take the water, his mode of making theſe *clay-drains*, as he calls them, is by digging to a certain depth with common ſpades; and at the bottom of the trench ſo opened he takes a ſpit, with a narrow ſpade that has a cutting edge. This tool opens a trench, which juſt receives a jointed wooden frame, with a chain at the end, by which it is drawn on by the application of a lever. This frame, fitting the ſpace left by the narrow ſpade, is covered with clay, rammed cloſe and firmly to it, being firſt wetted, that it may ſlide from this clay vault when drawn on by the lever: and from much experience he finds theſe drains perfectly ſafe and durable. Over the rammed clay mould, enough to fill to the ſurface is thrown in."

The writer alſo mentions, that in diſcourſing "with him on other applications of the power he exerts in drawing the mole, he informed him that Mr. Barker of Fairford has a water, that was ſo choked up with mud and weeds, that a duck could ſcarcely ſwim in it. He applied the windlaſs, frame, and chain, to drag out all; and with ſuch ſucceſs, that no other method would have cleanſed the water at ſo cheap a rate: ſome drag, ſcraper, or other contrivance, muſt of courſe be neceſſary for taking and retaining the mud," &c. And Mr. Young ſuppoſes, that "a very uſeful application of this power would be to the purpoſe of drawing turnips or cabbages from off wet land, which, by common carting, is attended with ſo much miſchief. He has ſeen temporary ſheds roughly erected, on the borders of turnip-fields in Suffolk, for ſtall-feeding beaſts: the addition of the windlaſs, to draw the turnips to ſuch ſheds, would be extremely important. Another application of this force, well deſerving attention, is, for drawing the machine which he has ſeen in the maritime part of Eſſex, wherewith croſs-roads are levelled. Where ruts are deep, and combs and quarters high, with other inequalities, this tool, a ſort of harrow, might be very cheaply uſed for effectually ſmoothing the whole, and improving the roads at a very ſmall expence." And as "much the moſt economical ſyſtem in which the thraſhing-mill can be applied is, that of a circular iron rail-way, whereon to draw the ſtacks to the mill, as he has fully explained in the 33d volume of the Annals: inſtead

ſtead of the application of the power of the wind or horſes to draw the ſtacks, the windlaſs and anchor of the mole-plough might be moſt cheaply applied. Another application of this power which he ſhall mention is, for the draught of ploughs and other machines, when comparatively tried: the force exerted would be more regular and ſteady than that of horſes, or even oxen; and the only attention particularly demanded would be to keep the chain parallel to the furrow, and at the right diſtance from it."

But Mr. Young ſuggeſts, that "in the operation of hollow draining itſelf, a moſt important deſideratum yet remains, and that is the drawing a plough that ſhall cut an open trench, for filling up with ſtraw, wood, or ſtone. Two ſuch ploughs have been invented: Mr. Arbuthnot's, a plate and explanation of which are to be ſeen in his "Eaſtern Tour;" and Mr. Makin's, which is kept in the Society's repoſitory in the Adelphi buildings. The trampling of ſo many horſes as theſe ploughs required, was the great objection to their uſe. This ſerious evil is done away in the windlaſs ſcheme; and he cannot but recommend to Mr. Lumbert's attention the improvement of one of thoſe ploughs, or the invention of another, for executing theſe drains by means of his windlaſs. He ſtates, that "in all ſorts of hollow draining, Mr. Lumbert is decidedly of opinion that the cuts ſhould be in the direction of, and with the ſlope of the land: not diagonally acroſs it, which is the common practice. In the latter method, the drains operate but on one ſide: cutting off the courſe of the water, as it deſcends, it drains the land only below the cuts; but if made with the ſlope, they operate equally on either ſide; and as he ſuppoſes the veins or pores of the ſoil, which conduct the water to act in every direction, provided the water itſelf is taken away, his cuts in the direction of the ſlope receive it laterally from every portion of the land between the drains, the deſcent from which to the bottom of the drain is greater than the angle of the deſcent of the natural ſurface of the field. It would not be eaſy to bring this opinion to the teſt of exact experiment; but a very ingenious farmer in Suffolk, Mr. Simpſon of Witneſham, near Ipſwich, has the ſame conviction, and has drained ſome hundreds of acres very ſucceſsfully upon this plan."

But the nature, uſe, and application of this implement may, however, be better underſtood from *fig.* 2, in *Plate Agriculture* (*Ploughs*), in which,

1. The beam.
2. The mole, to which ſegments for lengthening it ſcrew on at 3.
4. The roller at heel, on which it preſſes.
5. The chain, 50 to 60 yards long, which winds on to the two cylinders, 7, 7.
6. A pulley, around which the chain, 5, plays.
8, 8, 8, 8. Windlaſſes turned each by two women.
9. Stays, which entering the ground, aſſiſt in keeping the machine ſteady.
10. The anchor.

And the proportion and reſpective angles of all the parts may be meaſured by the ſcale which is given in the plate. See PLOUGH.

MOLE-*Traps*, the name of ſuch traps as are contrived for the purpoſe of taking and deſtroying moles. They are of ſeveral different kinds. See MOLE-*Catching*.

MOLE, *Mola*, or *Mola Carnea*, in *Phyſiology*, a miſ-ſhapen maſs of hard fleſh, ſometimes generated in the wombs of women, inſtead of a fœtus; called alſo a *falſe conception*. It is, however, a very rare production; what is called a mole by women being generally found on examination to be nothing more than coagulated blood. The following approaches neareſt to what the ancients conceived to be a mole, of any thing that has occurred to the writer of this article. A woman, about twenty-ſeven years of age, was delivered of a female fœtus, and its placenta, in which nothing uncommon was obſerved; and although the uterus remained of an unuſual ſize, yet the pains not recommencing, there was no ſuſpicion entertained but that its bulk was occaſioned by coagulated blood. On the third day the pains became violent, and this monſter was born. Its ſhape was ſpherical, but ſomewhat flattened. It meaſured in its largeſt diameter eight inches, and weighed about eighteen ounces. It received its nouriſhment by an umbilical cord, to which was attached a portion of membranes, and although no placenta was found, it is probable it had a ſmall one, and that it was incloſed in its own involucrum. It was completely covered with a cuticula, and a little above the part where the navel-ſtring terminated, there was a hairy ſcalp covering a bony prominence, ſomewhat reſembling the arch of the cranium. On diſſection it was found to be plentifully ſupplied with blood-veſſels, proceeding from the navel-ſtring, and branching through every part of it. It had a ſmall brain, and nerves paſſing from thence through the foramina of the bones; but no reſemblance of any thoracic or abdominal viſcera. The reſt of its bulk was made up of fat. This was inſerted, with the plate of the external appearance of the object, in the ſeventy-firſt volume of the Philoſophical Tranſactions.

MOLE, *Moles*, a maſſive work formed of large ſtones laid in the ſea by means of coffer-dams, extended either in a right line, or an arch of a circle, before a port; which it ſerves to cloſe; to defend the veſſels in it from the impetuoſity of the waves, and to prevent the paſſage of ſhips without leave.

Thus we ſay the mole of the harbour of Meſſina, &c.

MOLE is ſometimes alſo uſed to ſignify the harbour itſelf.

MOLE, *Moles*, among the Romans, was alſo uſed for a kind of mauſoleum, built in manner of a round tower on a ſquare baſe, inſulate, encompaſſed with columns, and covered with a dome.

The mole of the emperor Adrian, now the caſtle of St. Angelo, was the greateſt, and moſt ſtately of all the moles. It was crowned with a brazen pine-apple, in which was a golden urn containing the aſhes of the emperor.

MOLE, in *Zoology*. See TALPA, and the article MOLE, *ſupra*.

MOLE-*Cricket*, *Gryllotalpa*, in *Entomology*. See GRYLLUS.

MOLECULE, MOLECULA, in *Phyſics*, a little maſs or portion of any body.

The air, by reſpiration, inſinuating itſelf into the veins and arteries, endeavours by its elaſtic power to divide and break the molecules of the blood, which on their part reſiſt ſuch diviſion.

MOLEEAH, in *Geography*, a town of Bengal; 54 miles W.N.W. of Midnapour.

MOLENE, a ſmall iſland in the Engliſh channel, near the W. coaſt of France; ſix miles S.E. of Uſhant. N. lat. 48° 24′. W. long. 4° 52′.

MOLENES, a ſmall iſland in the Engliſh channel, near the coaſt of France; 13 miles W. of the iſland of Bas. N. lat. 48° 47′. E. long. 3° 33′.

MOLENPURG, a town of Auſtria; 16 miles S.W. of Crems.

MOLES CARNEA, in *Anatomy*, a name given by Veſalius, and others, to a muſcle called by Winſlow, Albinus, and others, the *complexus*. Spigelius calls it the *carnea moles trigemino adjuncta*.

MOLES *Carnea labia formans*, a name given by Fallopius to to the muscle called by Albinus *orbicularis oris*, and by Cowper *constrictor labiorum*.

MOLESTANDO. See Non *Molestando*.

MOLESWORTH, Robert, in *Biography*, viscount Molesworth of Ireland, descended from an ancient English family, was born at Dublin in 1656. Having received the elements of a good education, he was sent to complete his studies at Dublin college. He married, at an early age, the sister of the earl of Bellamont. When the prince of Orange came to England in 1688, Mr. Molesworth rendered himself conspicuous as a friend to liberty and the Protestant religion, for which he was afterwards attainted and his estate sequestered by king James's Irish parliament. The success of the Popish king, even in Ireland, was very short lived, and Mr. Molesworth was immediately noticed by king William, who raised him to the rank of privy-counsellor. In 1692 he was sent out envoy-extraordinary to the court of Denmark, where he resided three years. He had not, however, been very long in his situation before he found reason to be disgusted with the manners and habits of that newly enslaved country, and his eagerness to insist upon privileges which he conceived were his due in the high character of ambassador, gave offence, and he was forbidden to enter the court. Without the ceremony of taking leave, he withdrew to Flanders, on pretence of business, and thence returned to England, where he set about writing "An Account of Denmark." This work, written probably in resentment for the ill treatment he had met with, gave such an unfavourable account of the government and nation, that it was noticed by prince George of Denmark, consort to the princess Anne, afterwards queen of England, and a memorial was presented to king William, by the Danish envoy, complaining of the insult. It was undoubtedly one of the publications of that period which was most hostile to arbitrary power, and which exposed with the greatest freedom the arts by which public liberty was overthrown. Dr. King was employed to answer this work, in the performance of which, being furnished with facts by the Danish resident, he was enabled to detect some mistakes and misrepresentations: the book was however well received, and was translated into several foreign languages. For the author it procured the esteem and friendship of lord Shaftesbury, in unison with whose political principles he always acted. Mr. Molesworth was continued a member of the privy council till the latter part of the reign of queen Anne, when he was removed on account of a complaint from the clergy in convocation, to whose increasing influence he was always inimical. On the accession of George I. he was taken again into favour, and in 1716 was called to the house of lords in Ireland, by the title of viscount Molesworth. After this he spent his time chiefly in a literary retirement, connected with and much esteemed by several men of learning and liberal principles, among whom were Locke, Molyneux, and Toland. To the latter he was a warm friend and benefactor, though his own circumstances were narrow. Lord Molesworth died in 1725, at his seat near Dublin, in the sixty-ninth year of his age. Besides the work already referred to, he wrote an address to the house of commons for the encouragement of agriculture; and to his pen were ascribed several temporary publications in favour of the English constitution, and the general principles of liberty. One of his daughters, Mary, the wife of George Monk, esq. at her death, in 1715, left a collection of poems, which her father published, and dedicated to the princess of Wales, afterwards queen Caroline. Biog. Britan.

MOLEVETO, in *Geography*, a town of the island of Ceylon.

MOLFETTA, a town of Naples, in the province of Bari, on the coast of the Adriatic, the see of a bishop; eight miles E.S.E. of Trani. N. lat. 41° 18'. E. long. 16° 39'.

MOLIERE, John-Baptist Poquelin de, in *Biography*, the most celebrated of modern writers in comedy, was born at Paris in 1620. His father, who was valet de chambre upholsterer to the king, and kept a broker's shop, designed to bring him up to his own employment, and gave him a conformable education. The youth, without any advantages of education beyond those of mere reading and writing, imbibed a taste for literature, and was sent to the Jesuits' college as a day-scholar. His assiduity was soon observed; he became connected with Chapelle and Bernier, with whom he attended lectures in philosophy, under Gassendi. His father, with increasing years, became very infirm, and the business of the royal houshold was devolved on the son, and he attended Louis XIII. to Narbonne in 1641. On his return to Paris he resolved to devote himself to theatrical employments. He connected himself with a company of young persons, who acted in the suburbs of St. Germain, and assuming the name of Moliere, composed several little pieces of the comic kind, and performed his part on the stage. At length he joined La Bejart, a provincial actress, and they formed a company, which, in 1653, represented at Lyons his first regular comedy in verse, "L'Etourdi." This was followed by "Le Depit Amoureux," and "Les Precieuses ridicules," exhibited at Beziers, where Moliere was favourably received by the prince of Conti, who was chief of the states of Languedoc. He next visited Grenoble and Rouen, and from the latter came to Paris, under the protection of Gaston, duke of Orleans, who introduced him to Lewis XIV. He soon obtained permission to open a theatre in the metropolis, which was first in the old Louvre, and afterwards in the Palais Royal, and in the year 1665 he was placed in the service of the king, with a pension. He rose in reputation as a writer by the new pieces which he presented to the public, and became more and more perfect as he advanced in experience and observation. At mature age he married the daughter of the actress Bejart, who also followed the same profession, and he is said to have incurred very deservedly the same sort of ridicule as that which he bestows plentifully upon the poor husbands in his comedies. In friendship he was more happy, and he numbered among his intimates not only men of wit, but some of the greatest persons about the court. He died in consequence of his exertions in acting a principal part in his play, "Le Malade Imaginaire." He was labouring under a slight pulmonary complaint, and was strongly urged to postpone the representation: "What," says he, "will become of so many poor people who depend on it for the very means of subsistence. I should reproach myself for having neglected a single day to supply them with that of which they stand in need." He exerted himself with unusual spirit, and his efforts brought on the rupture of a blood-vessel, by which he was suffocated. This event happened in February, 1653, when he was only in the fifty-third year of his age. By almost the general consent of Europe, he is placed at the head of that genuine comedy which has for its subject the ridiculous in character and manners; and it is agreed that no one ever united more pleasantry in dialogue and incident, with more good sense and penetration in selecting just objects for comic satire. He is also regarded as the great reformer of the French theatre in respect to comedy, as Corneille was in respect to tragedy. His more serious compositions, and those written in verse, are by his countrymen esteemed his master-pieces, especially

especially the "Misanthrope" and the "Tartuffe." The latter, touching upon religious hypocrisy, excited a great clamour against him from the pretended devotees, who had interest to procure a prohibition of its second representation from the parliament. This temporary attack has not prevented the "Tartuffe" from retaining its place as one of the great ornaments of the French stage. Moliere had always a large portion of the philosophy of good sense, and rarely failed to discern the weak part of what he chose for the topic of his sarcasm. He had also a just sense of propriety in the conduct of life, and in serious humour he is always the friend of honour and integrity. His own character was, in many respects, estimable. He was kind, obliging, and generous. Nevertheless, after his death, the archbishop of Paris, Harlai, a man of loose morals, without, probably, half the good qualities of the actor, but desirous of pleasing the rigorists of the Roman church, refused him Christian burial, and the king's authority was requisite to procure him private interment in a chapel belonging to the church of St. Eustace. The bigotry of the mob, whom the priests had kept ignorant to make them engines in their own cause, impeded even this obscure ceremonial, and they could not be dispersed till money was given them for the purpose. "Such," says an able biographer, "was the treatment of a man who was an honour to his country, and who will ever rank among the principal ornaments of the age in which he lived! No one was more impressed by a sense of his merit than the great Conde, who, in reply to a wretched rhymer, that had brought him an epitaph on Moliere, "Would to heaven he had presented me with thine!" He is honoured with memorials by Boileau, Voltaire, and the king, who being asked to name the first writer that had appeared in his reign, named Moliere, without the smallest hesitation. His style in prose is perfectly natural and easy: in verse he has been accounted incorrect and careless. As an actor he excelled only in comedy: his voice was feeble and indistinct, but his strong features, animated by intelligence, rendered him the perfect representative of the characters, in his own pieces, which he took upon himself. His works have been a thousand times reprinted: the best edition is said to be that of Bret, at Paris, in six volumes, with commentaries. Moreri.

MOLIERES, Joseph-Prival de, a celebrated French priest and mathematician, who flourished in the eighteenth century, was born at Tarascon, in the county of Foix, in the year 1677. Owing to a tender and delicate constitution, he chose for himself a life of study, and became, in a short time, famous for his learning on divers topics, but particularly in the several branches of belles lettres and mathematics. His elder brother, who had obtained considerable rank in the army, having been slain in battle in 1695, M. Molieres' parents were desirous that he should settle in the world, but his love of study rendered their persuasions ineffectual. That he might put an end to all importunity on this head, he entered at once into the church, and was ordained priest in the year 1701. He afterwards entered in the congregation of the oratory, and taught the classics and philosophy with great success in several of their seminaries. Some years after this, having read and greatly admired the works of father Malebranche, he was anxious to become acquainted with their author; and for that purpose quitted the oratory and repaired to Paris. Here he attached himself closely to that philosopher, and during his stay in the metropolis, he presented several memoirs to the Academy of Sciences, and in 1721 he was admitted into it as an adjunct to the mechanical class. Two years afterwards he obtained the professorship of the College-royal, and in 1729 rose to the rank of associate in the Academy of Sciences. He had already published a work, entitled "Mathematical Lessons, &c.," in which the principles of algebra and arithmetical calculations are methodically laid down, and the theorems explained and demonstrated. After this, which was well received, he published four volumes of "Lectures on Natural Philosophy, containing the Elements of Physics determined solely by the Laws of Mechanics, &c." This was said to be a very whimsical performance, in which he endeavoured to unite the system of Descartes with the principles of Newton, and he attempted to rectify the ideas of the French, by the experiments of the English philosopher. In 1741 he published the first part of his "Elements of Geometry," intended as an introduction to his physical lectures. He was a very irritable man, which led him frequently into passions, of which one was the cause of his death in 1742. In other respects he was reckoned a very amiable character, but was apt to be so absent, or absorbed in his studies, as to appear almost wholly insensible to surrounding objects. His infirmity in this respect became known, and he was accordingly made the subject of depredations. A shoe-black, once finding him profoundly absorbed in a reverie, contrived to steal the silver buckles from his shoes, replacing them with iron ones. At another time, while at his studies, a villain broke into the room in which he was sitting, and demanded his money; Molieres, without rising from his studies, or giving any alarm, coolly shewed him where it was, requesting him, as a great favour, that he would not derange his papers. Moreri.

Molieres, in *Geography*, a town of France, in the department of the Lot, and chief place of a canton, in the district of Montauban; 10 miles N. of it. The place contains 2493, and the canton 6870 inhabitants, on a territory of $132\frac{1}{2}$ kiliometres, in seven communes.

MOLIETTA, a town of Naples, in Bari; eight miles E.S.E. of Trani.

MOLILLA, a town of Hindoostan, in Bednore; 10 miles E. of Bednore.

MOLIN, a town of Persia, in Khorasan; 16 miles N.W. of Zeuzan.

MOLINA, in *Biography*. See Molinists.

Molina, in *Geography*, a small town of Spain, in the province of Murcia, pleasantly situated on the borders of a valley, which is watered by the Sagara. It is surrounded by considerable plantations of all kinds of trees, and fertile rich gardens, embellished with oranges, lemons, olives, pomegranates, and palms. The streets are large, straight, airy, and pleasant: the number of inhabitants is about 3000. The parish church is a handsome structure, but deformed by bad paintings; eight miles N. of Murcia.

Molina, a town of Spain, and capital of a lordship in New Castile, situated on a river of the same name, which runs into the Tagus, 15 miles S.W. of it; 100 miles N.E. of Madrid. N. lat. 41° 8′. W. long. 2° 1′.

Molina, in *Botany*, Lamarck Dict. v. 4. 227. Cavan. Monadelph. 435. t. 263, so called by the writer last mentioned, in honour of John Ignatius Molina, author of a natural and civil history of Chili, from which Jussieu has adopted several genera, with most uncouth names. See Gærtnera.

MOLINÆA, so denominated by Commerson, according to Jussieu, in memory of Johannes Molinæus (Jean des Moulins,) to whose assistance Dalechamp had recourse in the composition of his laborious work, after John Bauhin had been driven away from Lyons by the bigotry of the Papists; his learning and excellent character having made him too conspicuous there for a Protestant, like his father at Paris.

(See

(See BAUHIN.) Commerfon, it feems, intended at the fame time to commemorate his friend Defmoulins, author of an arrangement of the plants about Clugni, publifhed in Durande's Flore de Bourgogne.—Juff. 248. Willd. Sp. Pl. v. 2. 329. Lamarck Illuftr. t. 305. (Trigonis; Jacq. Amer. 102? Juff. 248?)—Clafs and order, *Octandria Monogynia*. Nat. Ord. *Tribilatæ*, Linn. *Sapindi*, Juff. See CUPANIA, to which *Molinæa* and *Trigonis* are there referred by our excellent predeceffor, the Rev. Mr. Wood, on the authority of Mr. Dryander, or rather of Lamarck. From an examination of Commerfon's fpecimens, we have no doubt of the propriety of this meafure. We find an evident ftyle in *Molinæa*, though perhaps it may not be protruded till after impregnation; but this removes one of Willdenow's objections. As to the *arillus*, or tunic of the feed, Lamarck's plate, fig. *i*, feems to indicate one, though not perhaps fo remarkable as that in Plumier's Nov. Gen. t. 19. *Cupania*, being the oldeft name and unexceptionable, is neceffarily preferred to the above.

MOLINE', in *Heraldry*. A crofs moliné is that which turns round both ways at all extremities, though not fo wide or fharp as that faid to be anchored.

MOLINET, CLAUDE DU, in *Biography*, a learned French ecclefiaftic and antiquary in the feventeenth century, was born at Chalons, in Champagne, in the year 1620. Having been inftructed in the rudiments of learning at his native place, he was fent to Paris to go through his courfe of philofophy. Here he entered among the canons-regular of St. Genevieve of the order of St. Auguftine, and afterwards became attorney-general of that congregation. He might have been raifed to higher dignities, but his love of ftudy and retirement induced him to decline them. Medals and antiquities of various kinds were his favourite fubjects of purfuit, and having been attached to them from almoft his earlieft years, he had collected a confiderable cabinet, which he annexed to the library of St. Genevieve, together with other rarities and curiofities. He was employed by Lewis XIV. to arrange his cabinet of medals, and augment their numbers, as well as to purchafe agates and other precious ftones, of which father Molinet was reckoned an excellent judge. He added more than 800 medals to the royal collection, and was amply and nobly remunerated by his fovereign's liberality, of which the library at St. Genevieve fupplied abundant evidence; for the improvement of that inftitution was the prime object to which all the fruits of his labours were devoted. He died in 1687, at the age of fixty-feven. He is known as an author by learned notes to an edition of the letters of Stephen, bifhop of Tournay; "Hiftoria Summorum Pontificum a Martino V. ad Innocentium XI. per eorum Numifmata;" "The Cabinet of the Library of St. Genevieve;" "Reflections on the Origin of Secular Canons, and on the Antiquity of Canons-Regular;" and other works which difplay much learning, and will afford gratification to antiquarians. Moreri.

MOLINEUX's HARBOUR, in *Geography*, a bay on the S.E. coaft of Tavai-Poenammoo, the fouthern ifland of New Zealand. S. lat. 46° 24'. W. long. 189° 50'.

MOLINISTS, in *Ecclefiaftical Hiftory*, a fect in the Romifh church who followed the doctrine and fentiments of the Jefuit Molina, relating to fufficient and efficacious grace. Lewis Molina, after whofe name this fect was called, was a Spanifh Jefuit, and profeffor of divinity in the univerfity of Ebora, in Portugal. In the year 1588, he publifhed a book, to fhew that the operations of divine grace were entirely confiftent with the freedom of human will; and he introduced a new kind of hypothefis to remove the difficulties attending the doctrines of predeftination and liberty, and to reconcile the jarring opinions of Auguftinians, Thomifts, Semi-Pelagians, and other contentious divines. Molina affirmed, that the decree of predeftination to eternal glory was founded upon a previous knowledge and confideration of the merits of the elect; that the grace from whofe operation thefe merits are derived, is not efficacious by its own intrinfic power only, but alfo by the confent of our own will, and becaufe it is adminiftered in thofe circumftances, in which the Deity, by that branch of his knowledge, which is called *fcientia media*, forefees that it will be efficacious. The kind of prefcience, denominated in the fchools *fcientia media*, is that foreknowledge of future contingents, that arifes from an acquaintance with the nature and faculties of rational beings, of the circumftances in which they fhall be placed, of the objects that fhall be prefented to them, and of the influence which thefe circumftances and objects muft have on their actions.

The great antagonifts of the Molinifts were the Janfenifts.

MOLINO, in *Geography*, a town of Naples, in Abruzzo Ultra; 13 miles S.S.E. of Aquila.

MOLINOS, in *Biography*. See QUIETISTS.

MOLINOSISTS, in *Ecclefiaftical Hiftory*, a fect among the Romanifts, who adhere to the doctrines of Molinos. Thefe are the fame with what are otherwife called Quietifts.

MOLISE, in *Geography*, a city of Naples, which, though not the capital, gives name to the county or diftrict to which it belongs; 48 miles N.N.E. from Naples. N. lat. 41° 39'. E. long. 14° 25'.

MOLISE, *County of*, a province of Naples, having N. Abruzzo Citra, E. Capitanata, S. Lavora, and W. thofe which were denominated the ftates of the church. Of all the provinces of Naples, this is the fmalleft, being about 30 miles long, and 24 wide. It is fertile in corn, wine, and faffron, and affords plenty of game and filk. The capital is Campo-baffo.

MOLIVO, a fea-port town on the N.W. coaft of the ifland of Metelin, or Mitylene, built on rocks of bafaltes, precifely on the fpot formerly occupied by Methymna: it is commanded by a caftle almoft in ruins: its population may be eftimated at 2 or 3000 inhabitants, as well Turks as Greeks; its territory is formed of a plain of moderate extent, very fertile, and furrounded by volcanic mountains: its productions confift principally of oil, corn, and barley; it furnifhes a little wine and various fruits; and alfo cotton and feveral kitchen-garden plants; 20 miles N.N.W. of Caftro.

MOLL, a town of France, in the department of the Two Nethes, and chief place of a canton, in the diftrict of Turnhoul; 10 miles from Harenthals. The place contains 3694, and the canton 15,679 inhabitants, on a territory of 265 kiliometres, in five communes.

MOLLARU, a town of Hindooftan, in the circar of Rajamundry; 45 miles N.E. of Rajamundry.

MOLLE, in *Botany*, Cluf. Exot. 322. Tourn. Inft. 661, a barbarous name, of Peruvian origin. See SCHINUS.

MOLLE, in *Geography*, a town of Norway, in the province of Drontheim. N. lat. 62° 48'. E. long. 7° 36'.

MOLLE, in *Ichthyology*, the name of a fmall fpecies of whiting, common in the Mediterranean, and in the markets of Rome, Venice, &c. and called by authors the *afellus omnium minimus*, and the *merlangus*. It is a fpecies of *Gadus*; which fee.

MOLLE, Ital., *Mol*, Fr., *Mollis*, Lat. In the primitive fcale of Guido, the found B, when flat in the hexachord of F, was called B *molle*, fweet, foft, compared with B in the hexachord

hexachord of G, when it was called B-*durum*, harſh, and B-*quadro*, ſquare, from the form of the ♮, which was made like a Gothic B, or rather ♮ for half; a character ſtill retained by the Germans for B natural. In ſolmiſation, B-*durum* implies more than B ♮, and B *molle*, B ♭.

MOLLER, Henry, in *Biography*, a learned German Lutheran divine in the ſixteenth century, was born at Hamburgh in the year 1530. He officiated ſome time as paſtor to a church in the landgraviate of Heſſe with great reputation, and was honoured with the degree of doctor of divinity. He was much celebrated for his ſkill in biblical literature, and he particularly excelled in the knowledge of the Hebrew and Chaldee languages. During fourteen years he filled the chair of profeſſor of the Greek and the Oriental languages in the univerſity of Wirtemberg, of which he was probably deprived for refuſing ſubmiſſion to the famous "Form of Concord." He died at Hamburgh in 1589, in the ſixtieth year of his age. He was author of "Commentaries" on the book of Pſalms, and the prophecy of Iſaiah. He was likewiſe known as a poet. Moreri.

MOLLERUSA, in *Geography*, a town of Spain, in Catalonia; 10 miles E.N.E. of Lerida.

MOLLIDON, a town of Hindooſtan, on the Dooab; 18 miles N.N.W. of Etaya.

MOLLIENS-Vidame, a town of France, in the department of the Somme, and chief place of a canton, in the diſtrict of Amiens. The place contains 836, and the canton 12,456 inhabitants, on a territory of 232½ kiliometres, in 29 communes.

MOLLINARI, Simone, in *Biography*, was maeſtro di capella del Duomo at Genoa, and publiſhed, in 1605, "Concerti Eccleſiaſtici," as they are called; but theſe, which are in Dr. Aldrich's Collection of Muſic in Chriſt-church, Oxon, were only maſſes and motets, accompanied by inſtruments, which, about this time, became very common in Italy.

MOLLIS Portio. See Portio.

MOLLITIES Ossium. This curious and extraordinary diſeaſe may be defined to be a morbid ſoftneſs and flexibility of the bones, ariſing from a deficiency of the phoſphat of lime in their ſtructure. Whether their firmneſs and ſtability are loſt, in conſequence of this matter being too abundantly abſorbed, or of its not being duly and ſufficiently ſecreted, is a queſtion which we cannot undertake to reſolve. Some writers treat of the mollities oſſium with rickets; but although it is true, that, in both theſe diſeaſes, the bones loſe their natural ſolidity and proper ſhape, it appears to us that the two affections deſerve a marked diſtinction, inaſmuch as rachitis is an affection peculiar to childhood, and the bones only change their ſhape gradually; whereas the mollities oſſium has frequently been obſerved to afflict adults, and occaſion ſuch a ſoftneſs of the bones, that, in the extreme ſtage of the diſeaſe, they may be at once bent in any direction whatſoever.

The following caſe, drawn up by Mr. Gooch, will ſerve to impreſs the reader with an idea of the diſorder: "Mary Hayes, of Stoke-Holy-Croſs, near Norwich, in Norfolk, was born January 11, 1718, had never been married, and always lived a regular, temperate life. Her father was unhealthy, but it is not known to what diſeaſe he was ſubject; her mother was healthy, and ſhe herſelf was always looked upon as a ſtrong healthy girl, till about fifteen years of age, when ſhe fell into the green ſickneſs, and took various medicines to no purpoſe. She had no other complaints till October, 1748, when ſhe was ſeized with pains, univerſally attended with feveriſh ſymptoms; and thus ſhe continued ſome weeks, after which the pain was chiefly confined to her legs and thighs, but not increaſed by external preſſure.

"She broke her leg in June, 1749, as ſhe was walking from her bed to her chair, without falling down, and heard the bones ſnap. The fracture was properly treated by one of the ableſt ſurgeons, and due regard had to her indiſpoſition. No callus was generated; but in a few months the bones grew flexible, from the knee to the ankle. Thoſe of the other leg and thigh were viſibly affected ſoon afterwards, in the like manner; and both legs and thighs then became œdematous, and ſubject to be excoriated, diſcharging a thin yellow ichor. About this time," ſays Mr. Gooch, "I firſt ſaw her with the ſurgeon who had the care of her.

"The winter after breaking her leg ſhe had ſymptoms of the ſcurvy, and bled much at the gums.

"Many eminent phyſicians preſcribed for her, but without any effect, unleſs the regularity of her menſtruation, for the laſt eighteen months, be aſcribed to chalybeate medicines, which were part of their preſcriptions; though the ſame kind of medicines were formerly preſcribed, and long continued, without having that effect, even when ſhe was in a condition to take exerciſe.

"About a year before her death ſhe was removed to the pariſh ſhe belonged to, where I had an opportunity of viſiting her often, and obſerving the progreſs of her diſeaſe. She told me ſhe had found but little alteration of her complaints in general, for ſome time paſt, and thought her appetite and digeſtion rather mended. She breathed with difficulty, and her thorax appeared ſo much ſtraightened, as neceſſarily impeded the expanſion of the lungs. Her ſpine was much diſtorted, and any motion of the vertebræ of the loins excited extreme pain. Her legs and thighs being quite uſeleſs, ſhe was confined to her bed in a ſitting poſture. The bones ſhe reſted upon, having loſt their ſolidity, were much ſpread, and the ends of her fingers and thumbs, by frequent efforts to raiſe herſelf, were become very broad, with a curvature of their phalanges. *She now meaſured but four feet, though before this diſeaſe ſhe was five feet and a half high, and well ſhaped.*

"From this time," ſays Mr. Gooch, "I obſerved the flexibility of her bones became gradually more general, and the difficulty of breathing increaſed, with a waſting of her fleſh. For the laſt four months of her life ſhe had a total ſuppreſſion of the menſtrual diſcharge, and a great tendency in her legs to mortify, which had long been anaſarcous, and excoriated almoſt all over. She retained her ſenſes perfectly to the laſt, and but a few minutes before ſhe died, talked concerning her miſerable condition and approaching end, in a very rational and compoſed manner, with her nurſe, who perceived no ſigns of the change which was juſt at hand; then reclined her head, and expired inſtantly without a groan.

"Two days after her death, which happened on Feb. 6, 1753, her limbs being firſt well ſtretched out, ſhe was meaſured, *and found wanting, in her natural ſtature, two feet and two inches!* I opened the abdomen and thorax, removing the ſternum entirely, with ſome portion of the ribs, in order to gain at once a full view of thoſe cavities, and to obſerve how the viſcera contained in them had obſtructed each other in their reſpective functions, as well as to inſpect the ſtate of them. The heart and lungs were ſound, but flaccid, and much confined in their motion, to which the enormous ſize of the liver contributed in ſome meaſure, extending quite acroſs the abdomen, and bearing hard againſt the diaphragm, &c. The lungs did not adhere to the pleura, nor was the liver ſcirrhous; it was faulty only in its bulk. The meſentery was ſound, except one large ſcirrhous gland in it. The ſpleen was extremely ſmall. Nothing elſe was found obſervable in theſe cavities.

"All

"All her bones, except her teeth, were more or less affected, and scarcely any would resist the knife. Those of the head, thorax, spine, and pelvis, were nearly of the same degree of softness. Those of the lower extremities were much more dissolved than those of the upper, or of any other part. They were changed into a *parenchymous* substance, like soft dark-coloured liver, without the least offensive smell. I cut through the whole length, without turning the edge of the knife, and found less resistance than firm muscular flesh would have made, meeting only here and there with bony laminæ, as thin as any egg-shell.

"Those bones were most dissolved, which, in their natural state, are most compact, and contain most marrow in their cavities, &c."

Mr. Gooch further acquaints us, that the periosteum was rather thicker than ordinary; the cartilages thinner, but no where in a state of dissolution like the bones. He shewed specimens of the dissolved bones to sir John Pringle, in London, and then sent them to Dr. Hunter, who occasionally exhibited them in his anatomical lectures.

Mr. Gooch also sent some of the same substance to an ingenious chemist, desiring him to analyse it; the latter "could discover neither acid nor alkali prevailing in it; but that it contained near seven-eighths of an oleaginous substance, with a small portion of earth."

July 1753, Mr. Gooch saw a similar case to this in a woman, aged twenty-five, in the workhouse at Norwich, under the care of Mr. Swift, an ingenious man, and a very able surgeon. In this example, the ribs, having become exceedingly soft, "fell (to use Mr. Gooch's words) with the sternum flat upon the lungs," and obstructed respiration to such a degree, that when this gentleman saw her, she lay panting for life. In the other case, of which the narrative is given above, the ribs and sternum turned outwards, and the respiration was not quite so much obstructed.

Cases of the mollities ossium are recorded in the Philosophical Transactions; Mém. de l'Acad. Royale des Sciences; Act. Hafniens; German. Ephem. Forestus and Saviard have also detailed cases of the same disease; and a most remarkable example was published by Morand, at Paris, in 1752.

The causes of this singular disorder have hitherto baffled investigation. In the famous case of Madame Supiot, the patient had been in the habit of eating an extraordinary quantity of salt, and this circumstance was immediately suspected as the cause of the disease; yet, in other cases, the immoderate use of salt could not fall into suspicion, and Madame Supiot herself certainly continued to grow worse and worse, long after she had relinquished the custom of taking so much salt with her victuals. We are, therefore, justified in concluding that the eating of this substance had nothing to do with the production of the disease. Were salt capable of having this effect, sailors and others, who live so much on salted provisions, ought frequently to be afflicted with mollities ossium; yet this does not appear to be the fact.

With regard to the treatment, it does not appear that any successful method has been discovered. The deficiency of the phosphat of lime in the structure of the affected bones, has led to the suggestion of exhibiting this substance as a medicine. This may easily be done; but how to make the secerning arteries deposit it in the bones is a more baffling consideration. We know of no cases, in short, exemplifying the efficacy of this plan, though it is both rational and free from danger.

Madder, from its known property of tinging the bones red, has been supposed to have a particular action on the osseous system; but, says Boyer, it is now well ascertained, that it has no greater effect in rickets (which is a disease at all events analogous to mollities) than any other bitter plant. Malad. des Os, tom. ii.

MOLLUGO, in *Botany*, a name in Pliny, book xxvi. chap. 10, which he indicates as belonging to a plant rough both in foliage and flavour. Linnæus retains it for a genus of a smooth and tender habit, to which, if derived from *mollis*, it would be most suitable.—Linn. Gen. 42. Schreb. 58. Willd. Sp. Pl. v. 1. 491. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 184. Juss. 300. Lamarck Illustr. t. 52. Michaux Boreali-Amer. v. 1. 77. Gærtn. t. 130.—Class and order, *Triandria Trigynia*. Nat. Ord. *Caryophylleæ*, Linn. Juss.

Gen. Ch. *Cal.* Perianth inferior, of five oblong, slightly spreading, permanent leaves, internally coloured. *Cor.* none. *Stam.* Filaments three, bristle-shaped, shorter than the calyx, approaching the pistil; anthers vertical, oblong, cloven at the base. *Pist.* Germen superior, ovate, with three furrows; styles three, very short; stigmas obtuse. *Peric.* Capsule ovate, corrugated, of three membranous pellucid valves, and three cells; the partitions from the middle of each valve. *Seeds* numerous, roundish-kidney-shaped, polished.

Eff. Ch. Calyx of five leaves. Corolla none. Capsule of three cells and three valves. Seeds numerous.

1. M. *oppositifolia*. Opposite-leaved Mollugo. Linn. Sp. Pl. 131. (M. n. 52; Linn. Zeyl. 21. Jeonpala; Herm. Zeyl. 4. Alsine spergulæ facie Bengalensis, foliis angustis ad genicula binis, flosculis autem plurimis ad caulem radiatis, semine minutissimo fulvo; Pluk. Phyt. t. 75. f. 6.)—Leaves opposite, lanceolate. Branches alternate. Flower-stalks lateral, several together, single-flowered. Native of Ceylon. Linnæus describes it as "an annual *herb*, with long, diffuse, smooth, alternate *branches*. *Leaves* opposite, lanceolate, smooth, running down into *footstalks*. *Flower-stalks* several, axillary, equal, capillary, single-flowered. *Calyx* of five leaves."—Plukenet's figure, quoted at the suggestion of Burmann, answers pretty well to this description; and though it has the aspect of an *Hedyotis*, the inferior calyx, proper to *Mollugo*, is sufficiently indicated. According to Hermann this herb is eaten in sallads by the vulgar.

2. M. *stricta*. Close-leaved Mollugo. Linn. Sp. Pl. 131. Burm. Ind. 31. t. 5. f. 3. (Alsine multifolia floribunda glabra, ex sinu Bengalensi, foliis subrotundis, flore majore; Pluk. Almagest. 21. t. 257. f. 2.)—Leaves about four together, lanceolate. Flowers in panicled clusters, drooping. Stem erect, angular.—Native of Java and Bengal. *Root* fibrous, annual. *Stems* several, from two to twelve inches high, erect, slender, angular, smooth, bent at the lower joints, leafy. *Leaves* three, four, or more, at each joint, lanceolate, entire, smooth, of a pale glaucous green, tapering at the base into a sort of footstalk; in starved plants broader and shorter. *Stipulas* in pairs, small, membranous, roundish. *Flowers* very small, whitish, in long, slender, almost capillary, smooth clusters, collected into slight panicles; the partial stalks bent downward. *Capsule* roundish, very thin and membranous. *Seeds* almost black.

3. M. *hirta*. Hairy Mollugo. Thunb. Prodr. 24.—Decumbent. Leaves four together, obovate, hairy. Native of the Cape of Good Hope. Annual. Of this we have no further knowledge.

4. M. *pentaphylla*. Five-leaved Mollugo. Linn. Sp. Pl. 131. (Alsine ramosa procumbens quadrifolia, ad radicem polyphylla; Burm. Zeyl. 13. t. 8. f. 1.)—Leaves obovate; those of the stem four or five at a joint. Panicles cymose, somewhat racemose.—Native of various parts of the East Indies. This differs from *M. stricta* in having numerous

 stems

ſtems ſpreading circularly, nearly proſtrate, and obovate *leaves*. The *flowers* are twice as large, with a tawny hue, at leaſt when dried, and compoſe more denſe, level-topped, forked or cymoſe *panicles*, whoſe branches are ſcarcely racemoſe, and by no means elongated.

5. M. *nudicaulis*. Naked-leaved Mollugo. (Alſine foliis ad radicem poſitis; Burm. Zeyl. 14. t. 8. f. 2.)—Leaves obovate, all radical. Stems panicled, forked, naked. Flowers four-cleft. Native of Ceylon; *Burmann;* of Sierra Leone; *Afzelius*. Linnæus confounded this with the laſt, not perceiving that Burmann had figured two very different plants in his *tab*. 8, without numbering them; and he cites t. 8. f. 1, 2. This by an error of the preſs is become 12, which Willdenow copies. Burmann refers to a wrong ſynonym in Sloane, but he deſcribes the preſent ſpecies very well, as having all the *leaves* at the root, with very long, radical, *flower-ſtalks*, and four-cleft *flowers*, all which circumſtances diſtinguiſh it from the laſt.

6. M. *Spergula*. Spurrey Mollugo. Linn. Sp. Pl. 131. Burm. Ind. 31, t. 5. f. 4 (Pharnaceum Mollugo; Linn. Mant. 561. Willd. Sp. Pl. v. 1. 1508; but not Linn. Sp. Pl. 389, which is well figured in Herm. Lugd.-Bat. t. 21, and from which it appears, by his Mant. 562, Linnæus meant to diſtinguiſh the preſent ſpecies, intending probably to have called it *P. Spergula*, *P. Mollugo* being an error of the pen in p. 561.)—Leaves obovate, rough-edged, four or five together. Branches alternate, hairy at one ſide. Stalks axillary, ſingle-flowered.—Native of the Eaſt Indies. *Stems* procumbent, alternately branched, leafy, round, ſmooth, except a hairy lateral line. *Leaves* four or five at each joint, obovate, ſpreading, from two lines to half an inch long, rough or toothed at the edge; on ſhort, often woolly, *foot-ſtalks*. *Flower-ſtalks* axillary, ſolitary to each leaf, ſimple, ſingle-flowered, the length of the leaf. Linnæus deſcribes minute, linear, cloven *petals*, and five barren filaments, alternate with the five fertile ones, all which is hoſtile to the character of *Mollugo;* and removes this ſpecies to *Pharnaceum* at leaſt, if not elſewhere. We merely deſcribe it here to correct the above errors, and as being what he really meant for *M. Spergula*.

7. M. *verticillata*. Whorled Mollugo. Linn. Sp. Pl. 131. Willd. n. 5. (M. Spergula; Linn. Syſt. Nat. ed. 10. v. 2. 881. Alſine ſpergula mariana, latiori folio, floribus ad nodos, pediculis curtis circa caulem inſidentibus, calyculis elegantèr punctatis; Pluk. Mant. 9. t. 332. f. 4. A. erecta pentaphylla, flore albo; Burm. Zeyl. 13. t. 7. A. procumbens, gallii facie; Ehret. Pict. t. 6. f. 3.)—Leaves whorled, ſpatulate, unequal. Branches alternate, ſmooth. Flower-ſtalks ſhorter than the leaves, ſingle-flowered.—Native of Virginia. Cultivated in the Engliſh gardens in 1748, when Ehret delineated it. This ſpecies is a hardy annual, flowering from June to Auguſt. The *ſtems* are proſtrate, ſmooth, much branched, and widely ſpreading. *Leaves* obovate, acute, entire, ſmooth, tapering into a footſtalk; their length from half to one and a half inch. *Flower-ſtalks* ſeveral together, lateral, not axillary, capillary, deflexed, much ſhorter than the leaves. *Seeds* very prominent through the capſule, marked with dorſal furrows.

The botanical hiſtory of this genus is ſo confuſed, that though we have cleared it up in ſome degree, with the neceſſary aſſiſtance of the Linnæan herbarium, we are by no means certain that nothing more remains to be done. The ſpecies require to be confronted throughout with thoſe of *Pharnaceum*, a genus ſcarcely differing but in number of ſtamens, the moſt trivial of all poſſible characters in this tribe. See PHARNACEUM. S.

MOLLUSCA, in *Natural Hiſtory*, the name of the ſecond order of the Linnæan claſs of Vermes; and it includes animals that are naked; and furniſhed with tentacula or arms: for the moſt part they are inhabitants of the ſea; and by their phoſphoreſcent quality illuminate the dark abyſs of the waters. (See LUMINOUS *Animals*.) This order, which compriſes ſimple animals furniſhed with limbs, is ſeparated into diſtinct diviſions, claſſed according to the ſituation of the mouth, and the ſtructure of the body; thus:

In diviſion A the mouth is placed *above;* this diviſion includes the following genera:

Actinia,	Mammaria,
Aſcidia,	Pedicellaria,
Clava,	Salpa.
Dagyſia,	

In diviſion B the mouth is placed *before;* and in this are the

Derris and Pterotrachea.

In diviſion C the mouth is placed *before;* and the body has a lateral perforation. In this there are four genera, *viz*. the

Doris,	Limax,
Laplyſia,	Tethys.

In diviſion D the mouth is *before;* but the body is ſurrounded with feelers on the fore-part. There are two genera only, *viz*.

Itolothuria Terebella.

In diviſion E the mouth is *before;* and the body furniſhed with arms. Of theſe there are ſeven genera, *viz*.

Clio,	Scyllæa,
Lernæa,	Sepia,
Lobaria,	Triton.
Onchidium,	

In diviſion F the mouth is *before;* and the body furniſhed with peduncles or feet. In this there are the following five genera:

Amphitrite,	Nereis,
Aphrodite,	Spio.
Nais,	

In the laſt diviſion G, the mouth is placed *beneath;* and generally central. There are five genera in this, *viz*.

Aſterias,	Meduſa,
Echinus,	Phyſſophora.
Lucernaria,	

See VERMES.

MOLLUSCUM, in *Medicine*, an appellation applied by Dr. Willan to a ſingular cutaneous diſeaſe, of which there are not many caſes recorded. It conſiſts of numerous ſoft tubercles, containing an atheromatous matter, which are of various ſizes, from that of a vetch to that of a pigeon's egg, and of different forms, ſome being ſeſſile, and ſome attached by a neck. It is not uncommon to meet with one or two of theſe molluſca; but the ſingularity above alluded to is, that they ſometimes grow all over the ſurface of the body, and that without any diſorder of the general habit. They have no tendency to ulceration or ſuppuration, but continue permanent through life, having apparently no natural termination. The knife or ligature might be employed for the removal of thoſe which are attached by a peduncle; but the great number of theſe, independently of thoſe which are ſeſſile, deters from the attempt.

MOLMAN, in our *Old Writers*, a man ſubject to do ſervice. It is applied to the ſervants in a monaſtery.

MOLMA-

MOLMASECA, in *Geography*, a town of Spain, in the province of Leon; 20 miles W. of Aftorga.

MOLMUTIN, or MOLMUTIAN *laws*, the laws of Dunwallo Molmutius XVI. king of the Britons, who is faid to have begun his reign four hundred and forty years before the incarnation.

He was the firft who publifhed any laws in this land; and they continued famous therein till the time of William the Conqueror.

MOLNPATTY, in *Geography*, a town of the ifland of Ceylon; 18 miles N.W. of Trincomalee.

MOLOCH, in *Mythology*, the chief and peculiar deity of the Ammonites, who are faid, by Voffius and others, to have worfhipped the fun under this appellation, and to have facrificed their children to him. In the fcripture it is frequently afferted that the "Ammonites paffed their feed through fire unto Moloch." As to the meaning of this expreffion there is a confiderable difagreement among ancient and modern authors. The Jewifh writers very generally maintain, that the children were merely carried or led between two fires, by way of purification; whereas the Chriftian writers have been of opinion, that they actually burnt their children by way of facrifice to this grim idol. Near Jerufalem there was a place in which this horrid cuftom was obferved; it was called the valley of the fons of Hinnom, fo named, as it is faid, from the fhrieks of the children that were facrificed; and alfo Topheth, from a Hebrew word "toph," fignifying a drum or tabret, which they ufed, among other inftruments, to drown the dreadful outcries of the unhappy victims. The Canaanites in general were, in the days of Mofes, become incorrigible idolaters, and they are accufed of offering human facrifices to Moloch. See the paffage above cited from Levit. xviii. 21. From them this deteftable worfhip was tranfmitted to their defcendants the Phœnicians; and as the Carthaginians were a colony that came from Phœnicia, the firft gods of Carthage were the fame as thofe who were adored at Tyre and Sidon. The latter people are known to have worfhipped Saturn, and Saturn was the fame with Moloch, to whom they facrificed their children. Moloch was reprefented among the Ammonites under the monftrous figure of a man and a calf. About the feet of the ftatue were conftructed feveral furnaces, into which they threw the children whom they offered up to that god, and their cries were drowned, as we have already obferved, by drums and other mufical inftruments. Who this Moloch was, has been a fubject of various conjectures. Some fay that he was the fame as Priapus; others affert that he was the fun; but the moft common opinion has been, that he was the fame with Saturn; and as Saturn is thought to have been Abraham, it has been concluded that the worfhip of Moloch was formed upon the imperfect accounts which the pagans had collected concerning that ancient patriarch; and that all the circumftances of the facrifices offered to Moloch were expreffive of Abraham's adventures.

MOLOCHATH, in *Ancient Geography*. See MULUCHA.

MOLOCHI, in *Geography*, a town of Naples, in Calabria Ultra; three miles N.E. of Oppido.

MOLOCHITES, in *Natural Hiftory*. See MALACHITES.

MOLODIVE, in *Geography*, a town of the ifland of Ceylon, on a tongue of land feparated by a narrow channel from the E. coaft; 46 miles N. of Trincomalee.

MOLOGA, a town of Ruffia, in the government of Jaroflavl, at the union of the river Mologa with the Volga; 60 miles N.W. of Jaroflavl. N. lat. 58°. E. long. 38° 32'.

MOLOPS, a word ufed by fome medical writers to exprefs the purple fpots which appear upon the fkin in malignant fevers.

MOLOS, in *Geography*, a town of Arabia, in the province of Yemen; 16 miles N.N.E. of Jerim.

MOLOSSES, MOLASSES, or *Melaffes*, that grofs, yet fluid matter remaining of fugar, after refining, and which no boiling will bring to a confiftence more folid than that of fyrup; hence alfo called *fyrup of fugar*.

In the manufacture of fugar in the Weft Indies, the moloffes, not improperly called the treacle of fugar, is obtained by the following procefs. The curing-houfe, which is a large airy building, is provided with a capacious moloffes ciftern, the fides of which are floped and lined with tarras or boards. Over this ciftern there is a frame of maffy joift work without boarding. On the joifts of this frame empty hogfheads without headings are ranged. In the bottoms of thefe hogfheads eight or ten holes are bored, through each of which the ftalk of a plantain leaf is thruft, fix or eight inches below the joifts, and which is long enough to ftand upright above the top of the hogfhead. Into thefe hogfheads, the mafs from the cooler is put, which is called *potting*; and the moloffes drains through the fpongy ftalk and drops into the ciftern, from which it is occafionally taken for diftillation. For other particulars, fee the article SUGAR; and particularly the method of *claying* fugar.

The term *molaffes* has been ufed to denote the fediment of one kind of fugar called *chypre*, or brown fugar, which is the refufe of other fugars not to be whitened, or reduced into loaves. (See SUGAR.) Moloffes have been much ufed in Holland among poor people, for the preparation of tobacco, and alfo inftead of fugar.

MOLOSSES, *Artificial*. There has been found a method of making moloffes from apples, without the addition of fugar. The apple that fucceeds beft in this operation is the fummer-fweeting of a middle fize, pleafant to the tafte, and fo full of juice, that feven bufhels will yield a barrel of cyder. The manner of making it is this: the apples are to be ground and preffed, then the juice is to be boiled in a large copper till three quarters of it be evaporated: this will be done with a moderate fire in about fix hours, with the quantity of juice above mentioned; by this time it will be of the confiftence and tafte as well as the colour of moloffes.

This new moloffes ferves to all the purpofes of the common kind, and is of great ufe in preferving cyder. Two quarts of it put into a barrel of racked cyder, will preferve it, and give it an agreeable colour.

The invention of this kind of moloffes was owing to Mr. Chandler, of Woodftock, in New England, who living at a diftance from the fea, and where the common moloffes was very dear and fcarce, provided this for the fupply of his own family, and foon made the practice general among the people of the neighbourhood. It is to be obferved, that this fort of apple, the fweeting, is of great ufe in making cyder, one of the very beft kinds we know being made of it. The people in New England alfo feed their hogs with the fallings of their orchards of thefe apples; and the confequence of this is, that their pork is the fineft in the world. Phil. Tranf Nº 374. p. 230.

MOLOSSES *Spirit*, a very clean and pure fpirit, much ufed in England, and made from moloffes or common treacle diffolved in water, and fermented in the fame manner as malt or the common malt-fpirit. If fome particular art is not ufed in the making of this, it will not prove fo vinous as the malt-fpirit, but more flat and lefs pungent and acid, though otherwife much cleaner tafted, as its effential oil is of a lefs naufeous flavour. Whence if good frefh wine leys, abounding in in tartar, be duly fermented in the solution made thin for that purpose, the spirit will by that means become much more vinous and brisk, and approach more to the nature of the foreign spirits.

After the first distilling of molosses spirits from the wash into low wines, it is to be rectified, and in the succeeding rectifications proper additions are to be made. Alkaline salts, so common in the rectifying of the malt-spirits, must be avoided in this case, as not at all suiting this spirit, and the neutral ones only must be used, such as sandiver, common decrepitated salt, sal enixum Paracelsi, and the like; but upon the whole nothing so considerable is to be expected from these salts, as from a careful rectification in balneo Mariæ, without any other admixture; by this alone repeated two or three times with fresh water each time, the spirit will at once be made fit for the nicest uses.

Where the molosses spirit is brought to the common proof-strength, if it be found not to have enough of the vinosity in it, it will be very proper to add to it some good spiritus nitri dulcis; and if the spirit be clean worked, it may by this addition alone be made to pass on ordinary judgments for French brandy.

When newly distilled, this spirit, like all others, is colourless, and limpid as water; but our distillers always give it the same sort of yellow tinge, which the foreign spirits are found to obtain from the casks in which they are sent over. They have many ways of giving this colour extempore; but the two most in use are, either by an extract of oak-wood, or by burnt sugar.

Molosses spirit being occasionally dearer than that of malt, it is frequently met with basely adulterated with a mixture of that spirit, and indeed seldom is to be bought without some dash of it. Many have a way of mixing malt in the fermenting liquor; by this the yield of the whole is greatly increased, and the maker may assure the buyer that the spirit is pure as it ran from the worm.

England is the principal place where this spirit is made at this time: it was at one time prepared in great quantities in France, especially on the river Loire; but it has been forbidden there under a severe penalty. In Holland also they have it not, on account of the high duty laid upon treacle in favour of their own sugar-bakers.

We meet with very little of molosses spirit reduced to the strength of alcohol or spirit of wine, though, when rectified to this state in a proper manner, it is very little inferior to the real alcohol of wine, the name of which is so well known among us, though the thing itself is perhaps never seen here. All that we call spirit of wine being no other than malt spirit reduced to an imperfect alcohol, or a spirit almost totally inflammable.

Great quantities of molosses spirit are used in the adulterating of brandy, rum, and arrack; and great quantities are used alone in the making of cherry-brandy and other drams by infusion, in all which many prefer it even to the foreign spirits.

In most of the nice cases in our compound distillery, the molosses spirit supplies the place of a pure and clean malt-spirit, which we have not yet the way of producing in the large way to advantage. Our cinnamon, citron, and other fine cordial waters, are made with it; for the malt spirit would give these a very disagreeable flavour.

There is also another use to which this spirit serves extremely well, and in which even a foreign spirit that has any remarkable flavour will not do so well; this is the making of the extemporaneous wine, which some people are so fond of. See *Extemporaneous* WINE.

It gives a yellow stain to the hands, or other substances dipped into it: and may therefore be of use in dyeing. It is possible also, that the vinegar-makers may find use for it in their way; but the most advantageous of all its uses is to the distiller himself, a quantity of it added to new treacle intended for fermentation will be of great use in the process, and increase very considerably the quantity of spirit; but the proportion in regard to the new matter must not be too great. Shaw's Essay on Distillery.

For the method of extracting spirits from molosses in the West Indies, see the article RUM.

MOLOSSIS, in *Ancient Geography*, an inland province of the ancient kingdom of Epirus; which, according to Scylax, was only 40 stadia, or furlongs, in compass. It derived its name from Molossus, the son of Pyrrhus and Andromache, and contained the following cities, *viz.* Dodona, (which see,) Passaron, Tecmon, Phylace, and Horreum. See EPIRUS.

MOLOSSUS, in the *Greek* and *Latin Poetry*, a foot consisting of three long syllables, as *audiri, contabant, virtutem.* It takes its name either from a dance in use among the people called Molossi, or Epirotæ; or from the temple of Jupiter Molossus, where odes were sung in which this foot had a great share; or else because the march of the Molossi, when they went to the combat, was composed of these feet, or had their cadence. The same foot was also called among the ancients, *Vertumnus, extensipes, hippius, & canius.* Dion. iii. p. 475.

MOLRAUZEPOLLAM, in *Geography*, a town of Hindoostan, in the Carnatic; 10 miles N.W. of Madras.

MÖLSEN, or *Hohen* MÖLSEN, a town of Saxony, in Thuringia; 28 miles N.E. of Weimar. N. lat. 51° 10′. E. long. 12° 5′.

MOLSHEIM, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the district of Strasburg; 10 miles W.S.W. of Strasburg. The place contains 2534, and the canton 16,072 inhabitants, on a territory of $167\frac{1}{2}$ kiliometres, in 18 communes. N. lat. 48° 32′. E. long. 7° 34′.

MOLTA, or MOLTURA, a duty or toll paid by vassals to the lord for grinding their corn at his mill.

MOLTCHANA PIATSKIA, in *Geography*, a town of Russia, in the government of Tobolsk, on the Oby; 80 miles S.S.E. of Narim.

MOLTCHANOVKA, a town of Russia, in the government of Tobolsk, on the Oby; 92 miles S.S.E. of Narim.

MOLTEN GREASE, in the *Manege*. See GREASE.

MOLTER, in *Rural Economy*, the toll taken at a mill. See MOULTER.

MOLTIFAO, in *Geography*, a town of Corsica; 15 miles N. of Corte.

MOLTING, or MOULTING, the falling off or change of hair, feathers, skins, horns, or other parts of animals, happening in some annually, in others only at certain stages of their life. See MOULTING.

The generality of beasts molt in the spring.

The molting of a hawk is called *mewing.*

The molting of a deer is the quitting of his horns in February or March.

The molting of a serpent is putting off his skin. See EXUVIÆ.

MOLTON, SOUTH, in *Geography*, an ancient market and borough town in the hundred of the same name, and county of Devon, England, is situated on an eminence near the western banks of the river Moule, at the distance of 29 miles from Exeter, and 182 from London. Previously to the Norman conquest

conquest it formed part of the royal demesnes. It then came into the possession of private persons; and in the reign of Richard II. reverted to the crown. It was afterwards purchased by the burgesses: and the civil government is now vested in a mayor, eighteen capital burgesses, a recorder, town clerk, and two serjeants at mace. The town was represented in parliament in the thirtieth year of Edward I.; but no return has been made since that period. It is also remarkable for having been constituted an episcopal see, by an act passed the twenty-sixth of Henry VIII.; but it does not appear that any bishop was ordained. The parish church is a spacious structure, and contains several monuments. The guildhall is a convenient fabric; and the market place is extensive and well built. The number of houses was, in the year 1801, returned to parliament as 572, occupied by 2753 persons: of these many derive employment from the manufacture of serges, shalloons, and felts; and in obtaining lime from the various kilns in the neighbourhood. Provision is made for the education of the children of the more respectable natives, by a well-regulated free-school, founded in 1614, and of those of an inferior class by a charity-school: in the former the late judge Buller acquired the rudiments of that extensive legal knowledge, by which he afterwards became so distinguished. The town has the privilege of six annual fairs, and a weekly market on Saturday.

South Molton was the birth-place of the late Rev. Samuel Badcock, who acquired considerable literary reputation by his critiques on the authenticity of Chatterton's poems, and on other publications. He died in 1788, aged 41.

Between the towns of South Molton and Chumleigh, the Roman station Termolus is supposed to have been situated. It has been conjectured to have been near the junction of the rivers Taw and Mole; but antiquaries have not been able to identify the precise spot. The vicinity affords many remnants of Roman antiquity. Beauties of England and Wales, vol. iv.

MOLUCCA Balm, in *Botany*. See Moluccella.

Molucca *Bean*. See Bean.

Molucca *Nuts*. See Guilandina and Bean.

Molucca *Islands*, in *Geography*, islands in the East Indian sea, first discovered by the Portuguese in the year 1510. Strictly speaking, this appellation comprehends only the five following islands, *viz*. Ternat, Tidore, Motir, Makian, and Bakian or Batchian; but since the kings of the Moluccas have possessed territory in Gilolo, and other adjacent isles, and as the term *Molucca* islands is considered as synonimous with that of *Spice* islands, the appellation has been extended. (See Spice *Islands*.) The Moluccas, properly so called, having been discovered by the Portuguese, afforded to the Spaniards an inducement to make their first circumnavigation under the conduct of Magellan, a Portuguese commander. These two nations for some time contested the right of possessing these islands, till at length they were surrendered to the Portuguese, and from them they were wrested in 1607 by the Dutch. The opulent commerce in these seas was also claimed by the English; and in 1619 a treaty was signed, which declared the Moluccas, as well as Amboyna and Banda, common to both, so that the English were to have ⅓d of the produce and the Dutch ⅔ds: whilst each of these powers contributed its respective proportion for defending the islands from invaders. But a most atrocious plot was soon framed and carried into execution by the Dutch for rendering themselves independent of all competitors. As each of the islands will be described under its proper appellation, we shall not enlarge here.

MOLUCCELLA, in *Botany*, called *Molucca* by Tournefort, because it was supposed to grow in the Molucca islands. The name, as Linnæus has altered it, may be tolerated, but it is none of his best.—Linn. Gen. 296. Schreb. 392. Willd. Sp. Pl. v. 3. 128. Mart. Mill. Dict. v. 3. Sm. Prod. Fl. Græc. v. 1. 415. Ait. Hort. Kew. ed. 2. v. 3. 410. Juss. 115. Lamarck Illustr. t. 510. Gærtn. t. 66. (Molucca; Tournef. t. 88.)—Class and order, *Didynamia Gymnospermia*. Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, very large, turbinate, gradually terminating in a very wide, bell-shaped, toothed or spinous, incurved, permanent limb. *Cor.* of one petal, ringent, smaller than the calyx; tube and throat short; upper lip erect, concave, undivided; lower cloven into three segments, of which the middle one is most prominent and emarginate. *Stam.* Filaments four, under the upper lip, two of them shorter; anthers simple. *Pist.* Germen superior, four-cleft; style in size and situation like the stamens; stigma cloven. *Peric.* Capsule none. *Fruit* top-shaped, truncated, in the bottom of the open calyx. *Seeds* four, convex on one side, angulated on the other, broader upwards, truncated.

Obs. *M. spinosa* has the calyx with seven long spines; *M. lævis* has five small ones; and the calyx of *M. frutescens* is furnished with twelve spreading spines. In some species the calyx is longer than the corolla, in others shorter.

Ess. Ch. Calyx bell-shaped, dilated, much wider than the corolla, spinous.

1. M. *spinosa*. Linn. Sp. Pl. 821. Fl. Græc. t. 567, unpublished. (Molucca spinosa; Ger. em. 691.)—Upper lip of the calyx lanceolate, with a very long point; lower rounded, with seven spines. Leaves on stalks, ovate, palmate and cut.—A native of the Levant, and gathered by Dr. Sibthorp on mount Parnassus. It flowers in July and August.—*Root* annual. *Stem* about four feet high, erect, smooth, square, purplish, branched at the bottom. *Leaves* opposite, on longish stalks, strongly veined, smooth, dark green, palmate and cut. *Flowers* ten or twelve in a whorl, remarkable for the large pyramidal, upper tooth of their calyx, and the many radiating spines of the lower border. *Corolla* white, its upper lip hairy; palate streaked with purple.

2. M. *lævis*. Linn. Sp. Pl. 821. Fl. Græc. t. 566, unpublished. (Melissa Molucca lævis; Ger. em. 691.)—Calyx bell-shaped, slightly five-toothed; teeth equal, minutely spinous. Leaves on longish stalks, roundish or ovate, toothed.—Native of Syria, and found by Dr. Sibthorp between Smyrna and Bursa. Time of flowering like the last. *Root* annual. *Stems* about three feet high, branched, smooth, square, variegated with purple. *Branches* opposite, smooth. *Leaves* on long stalks, roundish, deeply notched or toothed, smooth, light green. *Flowers* axillary, about six in a whorl, the numerous whorls crowded together into a long spike, conspicuous for the rounded, reticulated calyxes which become tawny by age. *Corolla* white with a lilac tinge, shorter than the calyx.

3. M. *tuberosa*. Willd. n. 3. Pallas. It. v. 3. app. n. 101. t. T.—Calyx funnel-shaped, five-toothed; teeth equal, pointed. Stem-leaves nearly sessile, oblong wedge-shaped, toothed.—Native of muddy places, on hills in the south of Tartary, flowering in May and fruiting in July.—*Root* perennial, large, composed of two or three ovate knobs, occasionally simple, like a radish, and somewhat bitter. *Stem* erect, branched, jointed, divaricated, square, smooth, hairy at the joints. *Radical-leaves* on long rough stalks, ovate, deeply notched; those of the stem almost sessile, wedge-shaped, veined, nearly smooth. *Flowers* about three or four

four in a whorl, forming a loose spike. *Corolla* bright yellow, twice as long as the calyx.

4. M. *persica*. Willd. n. 4. Burm. Ind. 128. t. 38. f. 2.—Calyx funnel-shaped, five-toothed. Leaves sessile, wedge-shaped, serrated and spinous.—A native of Persia. Willdenow says that Linnæus confounded this species very erroneously with the following, *M. frutescens*, with which however it by no means agrees, except in habit. *Stem* simple, erect, very smooth, hoary, jointed, furnished with simple, long, unequal spines at each joint, generally from five to twelve in number. *Leaves* wedge-shaped, entire at the base, serrated at the end; the serratures terminating in downy spines. *Flowers* in dense whorls. Spinous teeth of the *calyx* minute. *Corolla* twice the length of the calyx. From Burmann's figure.

5. M. *frutescens*. Linn. Sp. Pl. 821. Fl. Græc. t. 568, unpublished. Allion. Pedem. n. 122. t. 2. f. 2.—Calyx funnel-shaped, five-toothed; teeth spinous. Leaves on short stalks, elliptical, obtuse, slightly five-toothed.—Found by Sherard in Italy, and by Dr. Sibthorp in the isle of Cyprus. *Stem* shrubby, much branched, round or nearly so, with downy branches. Spines at each joint four, awl-shaped, recurved. *Leaves* ovate, downy, on short stalks. *Flowers* axillary, solitary, their stalks about as long as the leaf-stalks. *Calyx* tubular, with five, broad, spinous teeth, nearly equal. *Corolla* scarcely exceeding the calyx, white, with purple streaks on the lower lip. We have separated the last species, which grows in Persia, from this, although professor Martyn is of opinion that they are the same plant; comparison, however, of Dr. Sibthorp's drawing with Burmann's figure shews them to be sufficiently distinct.

6. M. *grandiflora*. Willd. n. 6. (M. diacanthophylla; Pallas. Nov. Act. Petrop. v. 10. 380. t. 11.—"Calyx funnel-shaped, five-cleft, its segments pointed. Leaves sessile, in three, deep, cut segments."—Native of Tartary. We have seen neither specimen nor figure of this. Willdenow describes the *corolla* as longer than the *calyx*, its upper lip hairy and cloven.

Moluccella, in *Gardening*, comprehends plants of the herbaceous annual exotic kind, of which the species cultivated are; the smooth Molucca balm (M. lævis); and the prickly Molucca balm (M. spinosa).

Method of Culture.—These plants may be increased by sowing the seeds in the early autumn on a mild hot-bed, or in pots plunged into it, and when the plants have attained a little growth be planted in small pots, and placed under a hot-bed frame in winter, where they may have free air in mild weather by taking off the glasses, being carefully covered in frosty weather, keeping them pretty dry, otherwise they are apt to rot. In the spring the plants may be turned out of the pots, with the earth about their roots, and planted in a warm border, defended from strong winds, giving them a little water to settle the earth to their roots; after which they require no other care but to be kept clean from weeds, and be supported with stakes as there may be occasion.

These plants afford ornament and variety in the borders among other tender annual kinds.

MOLUCHES, in *Geography*, a tribe of Patagonians inhabiting the western part of the country. The dead among them are buried in square pits, in a sitting posture, with their weapons and drinking utensils; and an old matron annually opens the grave to cleanse and clothe the skeletons. Around are those of the slain horses, supported with props. The language of the Moluches is more copious and elegant than could have been expected, the verbs having three numbers, and as many tenses as the Greek. See Patagonia.

MOLUTA Arma. See Arma.

MOLWITZ, in *Geography*, a town of Silesia, in the principality of Brieg; three miles from Brieg.

MOLY, in *Botany*. See Allium.

This plant is supposed to have been wild rue, whose root is black, and the flower white, whence Ovid (Met. l. 14.) says:

> "Pacifer huic dederat florem Cyllenius album,
> Moly vocant superi, nigra radice tenetur."

According to Homer, Mercury gave this plant to Ulysses, by which he had evaded Circe's charms, the meaning of which is said to be, that he was thus taught to recover himself from his remissness, and to give counsel to his companions to quit so dangerous an abode. This plant, so difficult to be found, according to Homer, is the prudence which Ulysses exerted in extricating his soldiers from the seat of voluptuousness; and it may be supposed that all the transformations which Homer, Ovid, and the other poets say this princess wrought, were rather the effects of her charms and beauty than of her magic, though Horace (1 Epist. 2. 23.) leads us to understand, that they were the potions which she administered that produced these wonderful effects.

MOLYBDÆNA, Leadwort, a name given by some authors to the great toothwort, or dentillaria of Rondeletius. See Toothwort.

MOLYBDENUM, in *Chemistry*, a simple oxydable body and a metal. It is obtained from a blueish-black substance, which, till the experiments of Scheele, was confounded with plumbago. Like the latter substance, it has considerable lustre, feels as if it were greasy, and soils the fingers, but not to the same degree with plumbago.

Scheele found this substance to consist of sulphur and a white powder, which possessed acid properties, and which he denominated the *acid of molybdena*.

Bergman was the first who suspected this acid to be the oxyd of a metal. He accordingly requested Hielm in the year 1782 to make some experiments with a view to determine this fact. This experimentalist mixed the acid of this metal with linseed oil into the form of paste. This was exposed in a close crucible, lined with charcoal, to a very strong heat. By this means he succeeded in reducing the metal.

In order to obtain it in greater purity, he first roasted the ore to expel the sulphur, which reduced it to the state of powder. This powder being made very fine, he next dissolved it in ammonia, filtered the solution, and then evaporated it to dryness. By boiling this residuum with nitric acid he obtained a white powder, which was the molybdic acid. This being mixed with oil, and treated as before, afforded the metal in small grains.

This metal is so very infusible, that it has hitherto not been obtained but in small granulated bits. On this account we know very little of its physical properties. Its metallic nature, however, has been clearly made out, by the additional labours of Pelletier, Heyer, and others.

It is said to be of a greyish-white colour, possessing metallic lustre. Its specific gravity is supposed to be about seven.

We are indebted to Mr. Hatchett for some experiments upon the oxyds of this metal. He found it capable of four stages of oxydation; namely, the black, the blue, and the green oxyds, besides the white, which is the acid. These different oxyds, it appears, have been obtained by abstracting oxygen from the acid. The black is procured by heating the acid in contact with carbon, and the blue by a longer continuation of the same process. The latter is also obtained

 MOL

tained by immerfing a plate of tin into a folution of the acid.

The acid is obtained by diftilling nitric acid two or three times from any of the oxyds of this metal. The proportions of oxygen in molybdenum have not been afcertained, and till then we cannot, with much certainty, rely upon the number of its oxyds.

Molybdenum combines with fulphur. Indeed its native ore is a fulphuret. It is fingular that we have no accurate analyfis of the native fulphuret, as it might lead to fome knowledge of its other compounds. It readily combines with fulphur, and forms a fubftance fimilar to the native fulphuret.

If the acid be heated with fulphur in a clofe veffel, fuch as a retort, part of the fulphur combines with the oxygen and forms fulphurous acid; the remainder combines either with a leffer oxyd, or with the metal forming a fulphuret. Molybdenum combines with phofphorus, but the compound has not been examined.

Hielm, who firft reduced this metal, has fucceeded in alloying it with many of the other metals. He combined it with gold, platinium, filver, copper, iron, tin, nickel, zinc, lead, and fome others. None of thefe alloys, however, appear to be important, they are almoft all of them brittle.

MOLYBDIA, in *Natural Hiftory*, the name of a genus of cryftals. The word is derived from the Greek μολυβδος, *lead;* and expreffes cryftals altered in their figure by particles of that metal. The cryftals of this genus are of a cubic form, or compofed of fix fides, at right angles, like a dye. Of this genus there are three known fpecies.

MOLYBDIC Acid, in *Chemiftry*. This fubftance, to which we have already alluded, is arranged among the reft of the acids. Scheele, as has appeared under the account of the metal, was the difcoverer of this acid. We are indebted for additional facts relative to this fubftance, to Hatchett and Bucholz. It may be prepared by boiling nitro-muriatic acid upon the fulphuret for fome time; or, by diftilling this acid repeatedly from it, a white powder will be formed, mixed with fulphuric acid. This latter, being wafhed away, will leave the molybdic acid tolerably pure. Another method has been given by Bucholz. He directs the ore to be reduced to fine powder, and roafted at a red heat, gradually lowering the temperature, and ftirring it frequently, to keep the powder from adhering. This powder is of a grey colour, and contains a confiderable portion of the acid oxyd. This is digefted with foda or ammonia, which takes up the molybdic acid. It is remarkable, that molybdats of potafh and foda are colourlefs. May not the colour above-mentioned arife from abftraction of oxygen? For thefe facts we are indebted to Mr. Hatchett.

This acid forms infoluble falts with many of the metals. Hence it precipitates mercury, copper, lead, &c. from their folutions.

Tin filings change this acid into the blue oxyd, by abftracting fome of its oxygen.

Bucholz has attempted the analyfis of this acid. He digefted 100 grains of molybdenum with nitric acid, till the whole was converted into molybdic acid, which weighed 140 grains. He, therefore, concluded that the acid confifts of 100 of the metals, and 40 of oxygen, which gives in the 100, 67.1 of metal, and 32.9 oxygen. If the acid be the fourth oxyd of molybdenum, we may form fome idea of the other oxyds, and the reft of the compounds of molybdenum. If we take the acid at 33 *per cent.* of oxygen, and put the weight of the atom of molybdenum equal x, then

$\frac{x}{4 \times 7} = \frac{67}{33}$, and $x = 57$ nearly.

Hence for the protoxyd $\frac{57 + 7}{14} = \frac{100}{11}$, or 11 *per cent.* nearly. The fecond oxyd $\frac{57 + 2 \times 7}{14} = \frac{100}{20}$, or nearly 20 *per cent.* From thefe data, the third will contain 27 *per cent.* of oxygen. From the fame reafoning, taking the atom of fulphur at 13, the firft fulphuret will contain from 18 to 19 *per cent.* of fulphur.

MOLYBDOMANTIA, Μολυβδομαντεια, in *Antiquity*, a fpecies of divination, by obferving the motions, figures, &c. of melted lead.

MOLYN, Peter, in *Biography*. See Tempesta.

MOLYNEUX, William, an excellent mathematician and aftronomer, was born at Dublin in the year 1656. As his conftitution was naturally very tender, he was not fent to fchool, but inftructed in the elementary parts of learning by a private tutor at home. At the age of fifteen he was entered at Trinity college, in his native city, where he diftinguifhed himfelf for the vigour of his abilities, and the exemplarinefs of his manners; and having made a remarkable progrefs in academical learning, he was admitted to the degree of B. A. From Dublin college he went to London, and was entered a ftudent of the Middle Temple in 1675. Here he fpent three years, and obtained as much law as was neceffary for a gentleman who did not intend to follow it as a profeffion. The bent of his genius led him to devote much of his time to mathematical and philofophical purfuits, and he returned to his native country in 1678, where he married, and continued to profecute fuch branches of natural and experimental philofophy as were moft agreeable to his tafte. Being much attached to the principles of aftronomy, he began, in 1681, to make obfervations, and commenced a literary correfpondence with Mr. Flamftead, the aftronomer-royal of London. Shortly after this, he projected the defign of eftablifhing a Philofophical Society in Dublin, in imitation of the Royal Society, that had been but a few years eftablifhed in London under the aufpices of the king. Sir William Petty accepted the office of prefident, and our author was appointed the firft fecretary. The meetings of the fociety were held weekly, and by means of them Mr. Molyneux's fcientific reputation became widely extended, and procured him the efteem of perfons of the higheft rank, and, among others, of the duke of Ormond, then lord-lieutenant of Ireland, to whofe influence he was chiefly indebted for his appointment, jointly with fir William Robinfon, to the offices of furveyor-general of the king's buildings and works, and chief engineer. In 1685, he was elected fellow of the Royal Society at London, and in the fame year, for the purpofe of improving himfelf in the art of engineering, he obtained an appointment to view the moft confiderable fortreffes in Flanders. In the courfe of his tour he was introduced to Caffini, and the other celebrated aftronomers, in the places through which he paffed. Upon his return, in 1686, he publifhed his "Sciothericum Telefcopium, or A new Contrivance of adapting a Telefcope to an horizontal Dial, for obferving the Moment of Time by Day or Night." In 1687, when fir Ifaac Newton's "Principia" firft appeared, he expreffed his aftonifhment at fuch an effort of human intellect, at the fame time modeftly doubting if he fhould be able to comprehend all its parts. He was, perhaps,

haps, one of the first who was anxious to apply the principles, discovered in the book, to the practical purposes of religion: "One observation," says he, "is truly to be wondered at, and that is, the *sesquialtera ratio* between the periods and distances of the planets, and that not only among the primary erratics, but even among the lesser sets of dancers.—It is, in my opinion, an amazing thought to consider how universally this great law runs through the whole frame of nature, and agrees to bodies at such vast distances, and that seem to have no tie or respect to each other. It is to me, beyond exception, the strongest argument that can be drawn from the frame of the universe, for the proof of a God, to see one law so fixed and inviolable among those vast and distant *Chori*, who certainly could not therefore be put into this posture and motion by chance, but by an omnipotent intelligent Being." In 1688, owing to the confusion that existed at that period, the Philosophical Society of Dublin was broken up and dispersed; after Mr. Molyneux had distinguished himself by the communication of several papers upon curious subjects, some of which were sent to the Royal Society at London, and printed in their Transactions. During the following year, he, in common with a number of other Protestants, withdrew from the disturbances in Ireland into England. Mr. Molyneux, after a short residence in the metropolis, settled with his family at Chester, where he employed himself in arranging and correcting the materials which he had before prepared for his Dioptrics. The work was published in 1692, under the title of "Dioptrica Nova, A Treatise on Dioptrics, in Two Parts, &c." He gave it the title *Nova*, because it was almost entirely new, very little being taken from other writers, and because it was the first book that had appeared in English upon the subject. It contains several generally useful propositions for practice, demonstrated in a clear and easy manner, and the history of the discoveries made by several optical instruments. In the preface, the author notices the "Essay on the Human Understanding," which, he says, "has rectified more received mistakes, and delivered more profound truths, established upon experience and observation, for the direction of man's mind in the prosecution of knowledge, than are to be met with in all the volumes of the ancients." This compliment proved introductory to an acquaintance between the two philosophers, and a mutual correspondence was carried on by them as long as Mr. Molyneux lived, to whom, it is believed, many improvements in the second edition of Mr. Locke's work are to be attributed. When tranquillity was restored to Ireland, Mr. Molyneux returned, and was elected one of the representatives for the city of Dublin, in the parliament that was convened in 1692. In the following parliament, in 1695, he was chosen representative for the university, and held that seat during the remainder of his life. He was likewise nominated by the lord-lieutenant one of the commissioners of the forfeited estates, with a salary of 500*l. per annum*; but he declined the office, considering it to be an invidious employment. He was a zealous friend to the linen manufactory, and was at all times an open and avowed advocate for the freedom and independence of his country, and in this character he published "The Case of Ireland, stated in relation to its being bound by Acts of Parliament made in England," which is said to contain the substance of all that can be advanced on this very interesting subject, written with great clearness and strength of reasoning. The book was drawn up with great caution; nevertheless, a complaint was preferred against it to the house of commons, who thought proper to address his majesty on the occasion, asserting the dependency and subordination of Ireland to the kingdom of England. Mr. Molyneux, previously to the publication, had asked the opinion of Mr. Locke concerning the fundamental principle upon which his argument was founded; but this excellent man, instead of answering the letter of his friend, urged him to come to England, that they might talk over the subject together. To this he assented, and spent five of the happiest weeks in his life with Mr. Locke. When they separated, it was with an intention to renew the meeting in the following spring; but ere that arrived, death had deprived the world of Mr. Molyneux, who died in October, 1698, in the forty-third year of his age. He wrote several papers, that are inserted in the Philosophical Transactions, from vol. xiv. to xxix. Many of his letters are preserved in the collection of "Familiar Letters between Mr. Locke and several of his Friends." Biog. Brit.

Molyneux, Samuel, the only descendant of the preceding, was born at Chester in the year 1689. He was educated according to the plan laid down by the friend of his father, Mr. Locke. The progress of the child was very rapid, so that he knew more at the age of six or seven, than most children do at double that age. On the death of his father, the care of his education devolved upon an uncle, Dr. Thomas Molyneux, an eminent physician at Dublin, and a friend also of Mr. Locke, who executed the trust reposed on him with honour and fidelity. The young man, improving all the advantages bestowed upon him, became one of the most polished and accomplished gentlemen of his age, and was appointed secretary to the prince of Wales, afterwards king George II. As he was possessed of an ample fortune, he pursued, with great ardour, the sciences of astronomy and optics, and projected many schemes for their advancement. He applied himself to find out a convenient method of manufacturing specula for sir Isaac Newton's reflecting telescope, in which his chief design was to reduce the method of making these instruments to a sort of certainty, in order that the difficulty in constructing them, and the danger of miscarrying, might no longer discourage any workman from attempting to make them for public sale. With the assistance of Mr. Bradley, the Savilian professor of astronomy at Oxford, he succeeded so well, that the whole process, being communicated to a skilful optician, the construction of these telescopes was, afterwards, executed with great readiness and dispatch. His zeal for the improvement of his favourite sciences, induced Mr. Molyneux not only to collect and consider what had been written and practised by others, but also to procure a complete apparatus for the purpose of making new experiments. In the midst of these avocations, which were honourable to him as a philosopher, he was appointed one of the lords commissioners of the admiralty, by which means he became so involved in public affairs, that he had no leisure to promote the interests of philosophy and science. He accordingly gave all his papers to Dr. Robert Smith, professor of astronomy at Cambridge, whom he invited to make use of his house and instruments, in order to finish what he had left incomplete. By the death of Mr. Molyneux, which happened soon after this, the professor was precluded from the benefit of this invitation: he, however, supplied what was unfinished by our ingenious author from Huygens and others, and published the whole in his "Complete Treatise on Optics." Mr. Molyneux married lady Elizabeth, sister to the earl of Essex, but had no children. Biog. Brit.

MOLZA, Francisco Maria, a distinguished character among the Italian literati, was born in 1489, at Modena. From

From a very early age he was conspicuous for the readiness and avidity with which he imbibed classical literature: to his knowledge of the Greek and Roman languages, he added that of Hebrew. At the age of sixteen, he was sent to Rome to pursue his studies, but unfortunately he met with bad company, and entered upon a licentious course, which influenced the fortunes of the remainder of his life. To reclaim him, he was married to a Modenese young lady of noble descent, when he had scarcely attained to man's estate, with whom he lived till she had borne him four children. In 1576, he returned to Rome, where he spent almost all the remainder of his life. Study and pleasure seem alternately to have occupied all his thoughts. Among the many objects of his transitory attachments, is mentioned Furnia, a Roman courtezan, of whom he was so much enamoured, that it has been said he assumed the surname of Furnius on her account; but as his own mother's family name was De Forni, he probably derived the additional appellation from that. By these amours, he did serious injury to his reputation, and was once brought into the most imminent danger from the hand of an assassin; and he finally contracted a disease, the consequence of illicit connections, which brought him, as it has thousands, and tens of thousands of the votaries to pleasure, to a miserable end. From the year 1529 to 1535, Molza was at Rome in the court of cardinal Ippolito de Medici; after whose death, and the elevation of Paul to the popedom, he removed to that of cardinal Farnese. The profligacy of his conduct was no obstacle to an intimacy with many men of letters, such as Bembo, Sadoleto, Colocci, &c., and he was regarded as one of the principal ornaments of the literary academies then flourishing in that capital. His compositions were chiefly poems both in Italian and Latin, and on topics of all kinds, moral and serious, sportive and amorous, in all which he excelled. His elegies are excellent imitations of Tibullus. He was reckoned a powerful orator, and his epistles are graceful and elegant. He died, as we have already hinted, under the most excruciating sufferings, in 1544. Of his works, many were published separately, but no edition of the whole collectively appeared till that of Bergamo, in 1749, to which an account of his life is prefixed by Serassi.

Molza, Tarquinia, daughter of Camillo, the eldest son of the subject of the foregoing article, was born at Modena in 1542. She was instructed in the classics, in Hebrew, and in the belles lettres, and made great progress in every thing which she undertook: she became an adept in some of the abstruser branches of science, and was a proficient in music; but with all these, she was distinguished by the graces and amiable qualities of her sex. She was married, in 1560, to Paul Porrino, but never had any children; and after his death, in 1578, she passed her life in literary retirement at Modena, where she died in 1617. She distinguished herself by her writings, consisting of Latin and Italian poems, and translations from Plato, and other classics. Her remains were printed in the Bergamo edition of her grandfather's works. This lady was the subject of numerous eulogies from contemporary writers; but the most extraordinary honour that she received, was that of being presented with the citizenship of Rome, by the senate and people of that city, in a patent reciting her singular merits, and conferring upon her the title of *Unica*. The honour is extended to the whole noble family of Molza.

MOM, in *Geography*, a town of Arabia, in the province of Hedsjas; 5 miles N. of Mecca.

MOMAPANE Lake, a lake of Canada; 160 miles N. of Quebec. N. lat. 49° 40′. W. long. 71°.

MOMARACKPOUR, a town of Hindoostan, in Bahar; 21 miles N.W. of Chuprah. N. lat. 25° 59′. E. long. 84° 38′.—Also, a town of Hindoostan, in Allahabad; 30 miles N. of Gazypour.

MOMBAÇA, or Mombaza, a kingdom of Africa, near the coast of the Indian sea, south of Melinda, of unknown extent. The soil is very fertile, and produces rice, millet, and other grain, fruit-trees, and vegetables of various kinds: great numbers of cattle and of poultry are bred in this country; and it abounds with excellent springs of fresh water. The climate is temperate, and the air is healthy. The capital, formerly on a peninsula, has been insulated by cutting a canal across the isthmus. The houses are stone, cemented with mortar, and covered with paintings and other ornaments; the streets, though narrow, are straight, and the houses are contiguous, and terraced on the tops. The city is defended by a citadel, which served the Portuguese for a place of retreat, from which, however, they were expelled by an Arabian scheick in 1631; but they regained their possessions in 1729. Before the city is a commodious bay, being both spacious and affording deep water. From this port a considerable commerce is carried on with the neighbouring countries. The inhabitants are various in their complexion; but their dress is after the Arabian fashion. They differ also with regard to religion, as Christians, Mahometans and idolaters, are intermixed; but they are said to be more civil and hospitable to strangers than any others on the same coast. S. lat. 3° 30′.

MOMBEIRA, a river of Africa, in Benguela, which runs into the Atlantic, S. lat. 15° 15′.

MOMBEL, a town of France, in the department of Mont Blanc; 10 miles W.N.W. of Chambery.

MOMBELTRAN, a town of Spain, in Old Castile; 27 miles S.S.W. of Avila.

MOMBRIZO, Bonini, in *Biography*, an Italian man of letters in the 15th century, was born at Milan, and became professor of eloquence in that city. He was author of several works, which were well received, and among others some Latin poems, particularly one "On the Sufferings of Jesus Christ." His chief performance is entitled "Sanctuarium, sive acta vitæ Sanctorum," in two volumes. For this, it is generally admitted, that ecclesiastical historians are under great obligations to him, as he has drawn from obscurity many important and valuable facts, which, without his researches, would have been lost to the world. Of this work, subsequent writers have availed themselves; but a perfect copy of it is now exceedingly rare, and greatly sought for by curious collectors. Moreri.

MOMDSONA, in *Geography*, a town of Thibet; 9 miles S. of Lassa.

MOMEGASTRO, a town of Spain, in Aragon; 12 miles E. of Balbastro.

MOMELSDORF, a town of the duchy of Wurzburg; 9 miles N.W. of Ebern.

MOMENT, in *Time*, the most minute and indivisible part of duration; or what we otherwise call an *instant*.

A moment ought not to be conceived as the least part of time, but as a termination or limit of time. Maclaurin's Fluxions, vol. i. p. 245.

Moments, in the new doctrine of infinites, denote the infinitely small parts of quantity.

Moments are the same with what we otherwise call *infinitesimals*, and *differences*; being the momentary increments, or decrements of quantity, considered as in a continual flux. Moments are the generative principles of magnitude: they have no determined magnitude of their own; but are only inceptive of it.

Hence, as it is the same thing, if, in lieu of these moments,

 the

the velocities of their increases and decreases be made use of, or the finite quantities proportionable to such velocities; the method of proceeding, which considers the motions, changes, or fluxions of quantities, is denominated, by sir Isaac Newton, the method of fluxions.

Leibnitz, and most foreigners, considering these infinitely small parts, or infinitesimals, as the differences of two quantities; and thereby endeavouring to find the differences of quantities, *i. e.* some moments, or quantities infinitely small, which being taken an infinite number of times, shall equal given quantities; call these moments, *differences*; and the method of procedure the *differential calculus*. See Calculus *Differentialis*.

Moment, *Momentum*, in *Mechanics*, is the same with *impetus*; or the quantity of motion in a moving body. See Force.

Momentum is sometimes also used simply for the motion itself. Moment is frequently defined by the *vis insita*, or the power by which moving bodies continually change place. In comparing the motion of bodies, the ratio of their momenta is always compounded of the quantity of matter, and the celerity of the moving body; so that the moment of any such body may be considered as a rectangle under the quantity of matter, and the celerity.

And since it is certain, that all equal rectangles have their sides reciprocally proportionable; therefore, if the moments of any moving bodies be equal, the quantity of matter in one to that of the other, will be reciprocally as the celerity of the latter to the celerity of the former; and, on the contrary, if the quantities of matter be reciprocally proportionable to the celerities, the moments or quantities in each will be equal.

The moment, also, of any moving body may be considered as the aggregate or sum of all the moments of the parts of that body; and, therefore, where the magnitudes and number of particles are the same, and where they are moved with the same celerity, there will be the same moments of the wholes.

MOMENTARY Motion. See Quantity.

MOMFLOT, in *Geography*. See Monfalout.

MOMORDICA, in *Botany*, a name of whose derivation we find no satisfactory account. Linnæus deduces it from *mordeo*, to bite, because, he says, "the seeds seem to have been bitten." But this applies rather to the pulpy fruit, which, in the original species, cracks and flies asunder irregularly, so as to have that appearance. The name was first given to this plant by Castor Durante, and appears to be Italian, having originally belonged to some sort of *Geranium*. —Linn. Gen. 506. Schreb. 662. Willd. Sp. Pl. v. 4. 601. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 380. Juss. 395. Tourn. t. 29, 30. Lamarck Illustr. t. 794. Gærtn. t. 88.—Class and order, *Monoecia Syngenesia*; or rather *Monoecia Polyadelphia*; see Sm. Intr. to Botany, 478. Nat. Ord. *Cucurbitaceæ*, Linn. Juss.

Gen. Ch. Male, *Cal.* Perianth of one leaf, concave, in five lanceolate spreading segments. *Cor.* in five deep divisions, united to the calyx, but larger and more spreading, veiny and rugose. *Stam.* Filaments three, awl-shaped, short; anthers on two of the filaments double, or cloven, with two appendages at each side; on the third filament simple, with appendages on one side only, and consisting of a compressed body, with a pollen-bearing line once reflexed.

Female on the same plant. *Cal.* Perianth like that of the male, superior, deciduous. *Cor.* as in the male. *Stam.* Filaments three, very short, without anthers. *Pist.* Germen inferior, large; style one, cylindrical, columnar, three-cleft; stigmas three, tumid, oblong, directed outwards. *Peric.* Berry spongy, oblong, separating elastically, of three cells, with soft, membranous, distant partitions. *Seeds* several, compressed.

Eff. Ch. Male, Calyx five-cleft. Corolla deeply five-cleft. Filaments three.

Female, Calyx five-cleft. Corolla deeply five-cleft. Style three-cleft. Berry separating elastically.

1. M. *Balsamina*. Common, or Male, Balsam-apple. Linn. Sp. Pl. 1433. Lamarck Dict. v. 4. 237. Zorn Pl. Med. t. 45. (Balsamina mas; Ger. em. 362. B. mas, fructu puniceo, and Momordica fructu luteo-rubescente; Besl. Eyst. autumn. ord. 1. t. 4. f. 2, 3.)—Fruit roundish-ovate, pointed, angulated and tubercular. Bractea heart-shaped, toothed, above the middle of the flower-stalk. Leaves smooth, five-lobed, palmate, deeply toothed.—Native of the East Indies. A very tender annual in our gardens, kept occasionally for curiosity merely, notwithstanding its reputed vulnerary or balsamic virtues, from whence the specific name arose. The ripe fruit, infused in olive oil, said to possess a tonic and healing quality, is now out of use. The *stems* are long, weak, slender, smooth, leafy, supported by long, simple, spiral, capillary *tendrils*, opposite to each leaf-stalk. *Leaves* alternate, stalked, about two inches wide, of a bright shining green, naked, finely dotted, cut half way down into five, scarcely seven, broad, spreading lobes, with broad, sharp capillary-pointed teeth. *Flowers* large, yellow, on axillary, solitary, simple stalks, twice the length of the leaf-stalks, and bearing at the top a rounded *bractea*. *Fruit* about two inches long and one broad, orange-coloured, or almost scarlet, splitting at one side when ripe, and discharging its seeds with some force through the cleft, by means of the elasticity of its coat.

2. M. *Charantia*. Hairy Balsam-apple. Linn. Sp. Pl. 1433. I. Mill. Illustr. t. 83. (Balsamina cucumerina indica, fructu majore flavescente; Comm. Hort. v. 1. 103. t. 54. Amara indica; Rumph. Amb. book 10. 410. t. 151.) —Fruit oblong, taper-pointed, angulated and tubercular. Bractea heart-shaped, entire, below the middle of the flower-stalk. Leaves seven-lobed, palmate, bluntly toothed, somewhat hairy.—Native of the East Indies. Cultivated by Miller in 1731. It differs from the former in having a much longer *fruit*, more pointed at each end; *leaves* usually more deeply palmate, with broader more shallow teeth, their veins very hairy beneath; *flower-stalks* elongated, rather hairy, bearing their *bractea*, which is entire, in their lower part.

3. M. *muricata*. Muricated Balsam-apple. Willd. n. 3. (M. Charantia β; Linn. Sp. Pl. 1433. Lamarck Dict. v. 4. 239. M. zeylanica; Mill. Dict. ed. 8. n. 3. Pavel; Rheede Malab. v. 8. 18. t. 10.)—"Fruit oblong, muricated, taper-pointed. Bractea heart-shaped, nearly entire, below the middle of the flower-stalk. Leaves seven-lobed, palmate, toothed, pointed."—Native of the East Indies. The *leaves* of this are nearly smooth, less deeply lobed and toothed, with taper points. *Fruit* only an inch and half long, not furrowed, but beset with numerous sharp prominent points.

4. M. *senegalensis*. African Balsam-apple. Lamarck Dict. v. 4. 239. Willd. n. 4.—"Fruit ovate, acute, tubercular. Bractea heart shaped, entire, near the base of the flower-stalk. Leaves seven-lobed, deeply palmate, somewhat toothed, and rather hairy.—Gathered by M. Roussillon in Senegal. *Lamarck.* More hairy or downy than *M. Charantia*, the *leaves* smaller, more deeply lobed; *flower-stalks* generally longer; *fruit* shorter, being oval, and not above an inch long, warty; *flowers* small. *Lamarck.*

5. M. *operculata*. Covered Balsam-apple. Linn. Sp. Pl. 1433. Ait. Hort. Kew. ed. 1. v. 3. 499. Willd. n. 5. (M. ame-

(M. americana, fructu reticulato ficco; Comm. Rar. 22. t. 22.)—Fruit elliptical, angular, sharply tuberculated, with a beaked lid. Leaves five-lobed, toothed.—Native of the West Indies. Sent to Kew, in 1787, by Mr. Alex Anderson. It is annual like the rest, and flowers from June to September in the stove. The *leaves* are finely downy, with five shallow spreading lobes. *Tendrils* divided. *Fruit* ovate, or obovate, an inch and half long, its angles armed with pointed tubercles, its top a taper deciduous lid, leaving a small orifice, through which the seeds escape, the rest of the fruit when old becoming dry and reticulated.

6. M. *Luffa*. Egyptian Balsam-apple. Linn. Sp. Pl. 1433. (Cucumis ægyptius reticulatus, seu Luffa arabum; Vesling. Ægypt. 48. t. 50, 51. Petola; Rumph. Amb. book 10. 405. t. 147.)—Fruit oblong, somewhat cylindrical, furrowed, smooth; reticulated within. Male flowers corymbose. Bractea heart-shaped, entire, at the base of each partial stalk. Leaves rough, five-lobed, toothed.—Native of the East Indies. Cultivated near Cairo by the Arabs, (who call it *Luffa*,) rather, as it appears, for curiosity than use, the fruit not being eatable. This has the herbage more like some sort of Melon than the rest of the species. The *leaves* are rough with minute tubercles. *Tendrils* many-cleft. *Male flowers* numerous, pale yellow with orange streaks, in a downy corymbus, with small smooth *bracteas*. At the bottom of their long common stalk stands a solitary stalked *female flower*, whose long germen is clothed with dense down. The *stamens* are truly polyadelphous, with large sinuous anthers. *Fruit* a span long, swelling upwards, smooth, displaying, when the skin is removed, a most elegant reticulated structure, in which the seeds are lodged.—*Luffa fœtida*, Cav. Ic. v. 1. 7. t. 9, 10, is evidently nearly allied to this plant, but its stamens are said to be all separate. The angles of the fruit moreover seem to be sharper, and its coat thicker, opening by a lid, as in the last. The tendrils and inflorescence agree with *M. Luffa*, but, as Cavanilles observes, the two plants require to be compared in a living state, especially their stamens. See LUFFA.

7. M. *cylindrica*. Cylindrical Balsam-apple. Linn. Sp. Pl. 1433. Willd. n. 7.—Fruit cylindrical, very long. Bractea heart-shaped, entire, at the base of the flower-stalk. Leaves heart-shaped, angular, toothed.—Native of Ceylon and China. Of this we find no figure. The Linnæan specimen has an angular *stem*. *Tendrils* simple, very long. *Leaves* heart-shaped, finely toothed, rough, angular rather than lobed, on rough stalks. *Flowers* small, with very hairy stalks and calyx. *Fruit*, according to Linnæus, a foot long, rather hairy. *Seeds* black. *Flowers* yellow.—This seems by Willdenow to be cultivated in Germany, but we have it not.

8. M. *trifoliata*. Three-leaved Balsam-apple. Linn. Sp. Pl. 1434. Willd. n. 8. (Poppya sylvestris; Rumph. Amb. book 9. 414 t. 152. f. 2.)—Fruit ovate, prickly. Leaves ternate, toothed.—Native of the East Indies. Distinguished by its ternate *leaves*, which are smooth on the upper side; the leaflets all equally stalked. *Fruit* red, the size and shape of a hen's egg, rough with small prickly protuberances.

9. M. *pedata*. Pedate Balsam-apple. Linn. Sp. Pl. 1434. (M. fructu striato lævi, vulgò Caigua; Feuill. Peruv. v. 1. 754. t. 41.)—Fruit ovate, striated. Leaves pedate, serrated.—Native of Peru. We have never seen this but in the garden of the Marquis Hippolito Durazzo, at Genoa, in 1787. Feuillée says the Peruvians eat the fruit in their soups, its cooling qualities being peculiarly welcome in that hot climate. The *leaves* are dark green, rough with callous tubercles, and remarkable for being pedate; their lobes are pinnatifid, rather than serrated, in our specimen. *Flowers* small, greenish-yellow; the *male* ones umbellate; *female* solitary, at the base of their common stalk. *Calyx* with long, narrow, acute segments. *Germen* rough. *Fruit*, according to Feuillée, about four inches long, greenish-white, spongy, with a sharpish taste. He represents the *tendrils* as of two or three branches; in our's they are simple. This, with the deeply cut *leaves*, and their callous roughness, not mentioned in his prolix description, makes us suspect our's may be a distinct species. There is no specimen in the herbarium of Linnæus, as he merely copied Feuillée.

10. M. *lanata*. Woolly Balsam-apple. Thunb. Prodr. 13. Willd. n. 10.—"Leaves ternate, pinnatifid, rough. Fruit woolly."—Native of the Cape of Good Hope.

11. M. *echinata*. Bristly Balsam-apple. Muhlenb. MSS. Willd. n. 11. (Sicyos lobata; Michaux. Boreal-Amer. v. 2. 217.)—Fruit with four seeds, roundish, beset with long bristles. Leaves heart-shaped, roughish, with five sharp angular lobes, obscurely toothed.—Native of Pennsylvania, towards the river Ohio. We have specimens from the Rev. Dr. Muhlenberg. The *stem* is deeply furrowed, smooth. *Tendrils* long, divided, not many-cleft. *Leaves* on long stalks, opposite to each tendril, of a pentagonal figure, with five divaricated, pointed, distantly toothed lobes; heart-shaped at the base, where there is also a small additional lobe, or dilatation, at each side. Both surfaces of the *leaves* are rough with extremely minute prickles, especially on the ribs and veins, in our specimens, though Michaux and Willdenow describe them as smooth. *Flowers* small; the males very numerous, in axillary downy panicles, from two to six inches long: females solitary, stalked, at the base of the stalk of the panicle. *Germen* globose, beset with long weak prickles. *Fruit* roundish, the size of a gooseberry, likewise prickly, with only four seeds.

12. M. *dioica*. Dioecious Balsam-apple. Roxb. in Willd. n. 12.—"Fruit elliptical, muricated. Flowers dioecious. Leaves heart-shaped, pointed, toothed."—Native of the East Indies.—*Stem* angular, climbing. *Leaves* heart-shaped, undivided, pointed, toothed, smooth on both sides, two inches long. *Tendrils* simple. *Flowers* dioecious; the female ones axillary, solitary. *Fruit* the size of the first species, elliptical, very thickly beset with sharp tubercles. *Willdenow.*

13. M. *spicata*. Spiked Balsam-apple. Linn. MSS.—Leaves heart-shaped, slightly three-lobed, wavy, rough. Male flowers in long loose spikes, with fan-shaped, rough, toothed bracteas; female axillary solitary. Germen elliptical, rough.—Of this we find a specimen in the herbarium of the younger Linnæus, under the above name, but without any indication of its native country. The *stem* is furrowed, slightly prickly. *Tendrils*, as far as we can judge, simple. *Leaves* on long rough stalks, opposite to the tendrils, heart-shaped, with three or five slight angular lobes, wavy, rough with minute callous tubercles, the veins hispid. *Male flowers* in lax, simple, solitary, axillary, long-stalked spikes, each flower accompanied by a large, sessile, fan-shaped, rough *bractea*, toothed at the summit; *female* solitary, on a short axillary stalk; its *germen* elliptical, furrowed, hispid; *calyx* with a very long tube.—The male inflorescence marks this as a very distinct species, that seems not to be any where described.

14. M. *Elaterium*. Squirting Balsam-apple or Squirting Cucumber. Linn. Sp. Pl. 1434. Bulliard t. 81. (Cucumis sylvestris; Camer. Epit. 946. C. asininus; Ger. em. 912.)—Fruit elliptical, hispid, elastic at the base. Leaves heart-shaped, wavy, rough. Tendrils none.—Native of waste ground in the south of Europe. It is a hardy annual,

annual, now and then allowed a place in curious gardens for the ſake of its fruit, which, to the ſurpriſe of thoſe who touch it unawares, ſtarts from its ſtalk with a violent ſpring, ſquirting out the ſeeds by the orifice. The *herb* is a rank, ſpreading, rough and hairy, rather glaucous, weed, with round thick branches, deſtitute of tendrils. *Flowers* dull yellow; the males but few together in an axillary cluſter, accompanied at the bottom by one female bloſſom. *Fruit* pendulous, elliptical, blunt at each end, about two inches long, green, rough with innumerable ſmall briſtles, of a thick coriaceous texture, without valves.—The extract of this fruit, known by the name of ELATERIUM, (ſee that article,) is a violent and dangerous purge.

MOMORDICA, in *Gardening*, contains plants of the annual trailing and perennial kinds, of which the ſpecies cultivated are, the common momordica, or male balſam apple (M. balſamina); the hairy momordica (M. charantia); the Egyptian momordica (M. luffa); and the elaſtic momordica (M. elaterium).

Method of Culture.—All theſe plants may be increaſed by ſowing the ſeeds of the firſt three ſorts upon a moderate hot-bed, in the early ſpring months, as about March; and when the plants have had a little growth, let them be pricked out into another hot-bed, freſh air being given in fine weather, and water occaſionally; or they may be let remain in the firſt hot-bed till they have acquired ſufficient growth, and have four or five leaves, when they ſhould be removed into the hot-bed where they are to remain, one or two plants being put into each light, due ſhade and water being given till freſh rooted. They afterwards demand the ſame management as the cucumber kind, the branches being ſuffered to extend themſelves in the ſame manner. When thus managed, and properly treated, in reſpect to air and water, they produce fruit and ripe ſeeds in the latter end of ſummer, when it muſt be immediately gathered, to prevent its being diſperſed. The plants may likewiſe be ſet in pots, and placed in the hot-houſe, their vines or ſtems being ſupported by ſticks, in which mode they have a much better appearance and effect.

The fourth ſort may be ſown or ſuffered to ſcatter, where the plants are to remain, or on beds of fine mould in the autumn, the plants being afterwards thinned out, or removed into rows in an open ſituation, three or four feet apart, and as many diſtant in them, requiring only the further culture of being kept clean from weeds. Where the ſoil is dry, they often continue three or four years.

All the ſorts afford ornament, the firſt three ſorts in the ſtove, and the laſt in the open borders. The fruit of the laſt alſo affords a medicinal ſubſtance by inſpiſſation.

MOMORDICA, *Stinking*. See BRYONIA.

MOMOT, in *Ornithology*. See RAMPHASTOS *Momota*, and MOMOTUS.

MOMOT *Pheaſant* of Latham. See PHASIANUS *Motmot*.

MOMOTUS, in *Natural Hiſtory*, a genus of birds of the order Picæ, of which there is but a ſingle ſpecies: the generic character is, bill ſtrong, ſlightly curved, ſerrate at the edges; noſtrils feathered; tail wedged; feet greſſorial.

Species.

BRASILIENSIS, or Braſilian Momot. Green; front blueiſh-green; hind-head violet; crown black. This bird, remarkable for the beauty of its plumage, is a native of South America, and ſeems to be chiefly found in Braſil, whence it derives its name. It was firſt deſcribed by Hernandez, in his Hiſtory of Mexico; who ſays, "It is the ſize of a dove, and has ſcarlet eyes, with a black pupil; a crooked blackiſh bill, almoſt three inches long, ſharp-pointed, with the lower mandible ſhorteſt, and the upper ſerrated; the head is blue like that of the peacock; the legs and feet brown, and the reſt of the bird green; and what is extraordinary, is, that the tail has one quill longer than the reſt, and feathered only at the end." This deſcription was regarded by Ray as very inaccurate, and in his edition of Willoughby's Ornithology, he ſays, "This is, I dare ſay, more ſtrange than true, for the tails of all birds, I ever yet ſaw, have their feathers growing by pairs, that is, two of a ſort, on each ſide." Edwards, about half a century ago, deſcribed it as a ſpecies of Roller, and named it the "Saw-billed Roller." According to this naturaliſt, "It is ſhort-legged in proportion, and not long-winged; the bill is pretty ſtraight, moderately bending downwards at the point, toothed on the edges like a ſaw; the upper mandible duſky, the lower fleſh-coloured towards its baſis; the noſtrils are covered with ſmall black feathers, and ſome black briſtles pointing forward round the upper mandible; the upper part, and the ſides of the bill are encompaſſed with black, from which run black lines through the eyes, and broader black liſts, mixed with a little blue, from the corners of the mouth down the ſides of the neck; the top of the head is of an ultramarine blue, though next the bill inclining to ſea-green; in the middle of this blue ſpace, on the crown of the head, is a black ſpot; it has alſo a ſpot of black feathers, edged with blue, on the fore part of the neck, a little below the throat; otherwiſe the whole underſide, from the bill to the covert-feathers beneath the tail, is of an olive or greeniſh buff colour." Other naturaliſts have given deſcriptions rather different. Linnæus conſidered it as a ſpecies of the Ramphaſtos, or Toucan genus, and denominated it "RAMPHASTOS *Momota*;" but Dr. Latham inſtituted for it a ſeparate genus, the ſtructure of the feet forbidding it to be aſſociated with the Toucans, which have ſcanſorial or climbing feet, having the toes placed two forwards and two backwards, as the parrot genus. Edwards had noticed as a great ſingularity in this bird, that the two long tail-feathers ſeem as if they were ſtripped of their webs on each ſide for an inch ſpace, a little within their tips; but Latham ſays, "That though the tail, in many ſpecimens, exhibited the very remarkable particularity deſcribed by Edwards, yet in its truly natural, or perfectly complete ſtate, the two middle feathers are entirely webbed throughout their whole length." The momotus is nearly equal in ſize to a magpie, meaſuring about eighteen inches in length. It is ſaid to be a bird of ſolitary habits, frequenting thick woods, and is ſeen ſingly. It makes its neſt on the ground, ſometimes in the deſerted hole of an armadillo, or other quadruped; it is compoſed of dry graſs and ſtalks, and it lays commonly two eggs.

In Gmelin's laſt edition of Linnæus, there is a variety mentioned, and deſcribed as variegated with green, tawny, blue, and cinereous. The body above olive green, beneath ruſty; head large; crown blue, black in the middle; bill black, ſcarcely two inches long; the legs are black, and the claws hooked.

This bird feeds on inſects and raw fleſh, the fragments of which it macerates in water; when taken it ſtrikes violently with the bill; the voice is harſh, weak, and tremulous. Shaw, Latham. Gmelin's edit. of Linnæus.

MOMPOX, or *Santa Cruz de Mompox*, in *Geography*, a town of South America, in the province of Carthagena, on the left bank of the Magdalena; 110 miles S.S.E. of Carthagena. Mompox, which is a very commercial port, has a royal cuſtom-houſe, and a handſome quay of conſiderable height, as the river riſes regularly 12 or 13 feet in the beginning of December. N. lat. 9° 19'. W. long. 74° 11'.

MOMUS, in *Mythology*, was, according to Heſiod, the ſon

M O N

fon of Night and Sleep, and was fuppofed both by the Greeks and Romans to be the god of buffoonery and jefts. Satirical to excefs, he made even the gods, and Jupiter himfelf, the objects of his moft pungent raillery. None of the ancients have exhibited him in his true and lively colours more appropriately than Lucian. Momus is faid to have derived his name from the free and bold manner in which he cenfured the vices and defects of others; Μωμος in Greek implying cenfure. It was he who found fault with the gods, becaufe, in the formation of man, they had not made a little hole or window in his breaft, that one might have feen into his heart what were his thoughts: though Vitruvius afcribes this reflection to Socrates.

MONA, in *Geography*, or LA GUENON, a fmall ifland in the Weft Indies, between Hifpaniola and Porto Rico. N. lat. 18° 10′. W. long. 68° 28′.

MONA, in *Ancient Geography*, an ifland of Great Britain, now called Anglefea, the ancient feat of the Druids; which was firft attempted by Suetonius Paulinus, and afterwards reduced by Agricola. In the Britifh tongue it was called Môn, and when conquered by the Englifh, Anglefey, that is, Englifh ifland. See ANGLESEY.

MONACHUS, in *Zoology*, a fpecies of *Phoca*; which fee.

MONACHUS, in *Ornithology*, a fpecies of *Vultur*; which fee.

MONACO, in *Geography*, was, before the French revolution, a fmall principality of Italy, fituated on the coaft of the Mediterranean, between the county of Nice and the Genoefe territory, and about four or five Italian miles in circuit. The chief line of the Grimaldi, who had governed this principality for 800 years fucceffively, failed in 1731; but the eldeft daughter of Antony Grimaldi, having been, in 1715, declared heirefs of the principality, was married to Francis Leonorus, count de Torrigny; and the fruit of this marriage was Honoratus Camillus Leonorus, who adopted the name and arms of Grimaldi. Monaco is now united to France.

MONACO, a town of France, and principal place of a diftrict, in the department of the Maritime Alps, late capital of the principality above-mentioned, and the refidence of the duke. It is a fmall town, with narrow ftreets, fituated on a rock near the fea: it is fortified and has a garrifon and a good harbour, and poffeffes a right of compelling all fhips that pafs by to put in and pay toll; 6 miles N.E. of Nice. The place contains 1130, and the canton 3730 inhabitants, on a territory of $37\frac{1}{2}$ kiliometres, in 4 communes. N. lat. 43° 43′. E. long. 7° 22′.

MONACONDA, a town of Hindooftan, in Tellingana; 8 miles W.S.W. of Warangole.

MONAD, in the *Philofophy* of Leibnitz, is a fimple fubftance without parts. The exiftence of monads muft be admitted, fince without thefe no compound or aggregate of fimple fubftances could exift. Thefe fimple fubftances are properly called monads, becaufe, as unity is the fountain and origin of numbers, and comprehends all their powers, fo fimple fubftances are the matter of which all corporeal maffes are formed. Since monads have no parts, they have neither extenfion, figure, nor divifibility. They are the true atoms of nature, and elements of things, incapable of deftruction, except by the power of God. Each monad differs from every other; for it is impoffible that any two things fhould be found in nature perfectly alike. Monads have an internal principle of variation, by which they are continually varying in a certain manner; and hence arifes a plurality of properties and relations. This perpetually varying ftate, which involves and reprefents multitude in unity, is perception, which is not, however, to be confounded with confcioufnefs. The action of the eternal principle of monads, by which a tranfition is made from one perception to another, may be called appetite. The perception and appetite of monads are not to be explained mechanically by figure and motion, becaufe they are affections of a fimple fubftance without parts. In monads, therefore, nothing is found but perception and appetite; and in this refpect all monads may be faid to partake of the nature of foul; although that term is more properly applied to thofe living beings, which have diftinct perception united with memory. The prefent ftate of monads arifes from the paft, and perception from perception, as motion from motion. Monads are, in a ftate of perception, fimilar to that of a mind in a ftupor, which has a perpetual fucceffion of minute and indiftinct perceptions. God alone, fays Leibnitz, is primitive unity, or fimple original fubftance, from whom are produced all created or derived monads. Thefe owe their exiftence to the effufion of the rays of divinity, limited in their effects by the finite capacity of the creatures who receive them. Creatures have not proceeded neceffarily from the divine effence, but have been created, according to the plan of the divine underftanding, by the energy of the divine will and power; and their continued prefervation is a continual creation.

Monads have univerfally an influence on each other, and are reciprocally active and paffive. They are active, in proportion as their perceptions are diftinct; paffive, as they are confufed. In fimple fubftances, the influence of one monad upon another is not mechanical, but ideal, and is not effected without the intervention of the Deity, who directs them according to the ideas of his own intellect. From the univerfal influence of all creatures upon each individual, and of each upon all, it follows, that every fimple fubftance receives an impreffion or image of all the reft, and becomes, as it were, a perpetual living mirror of the univerfe. As the fame city viewed from different places appears different, and is optically multiplied; fo it happens, that in confequence of the infinite multitude of fimple fubftances in nature, pictures of the univerfe are multiplied without end, according to the different points of fight of different monads. By thefe means, all poffible variety, and, confequently, all poffible perfection, is produced in the univerfe. Since there is in nature a univerfal *plenum*, the motion of any body or compofition of monads muft affect every other body by means of intervening bodies; and every prefent motion will have a neceffary connection with every other future motion; whence he who fees all things can read in the prefent whatever will happen in any future time or diftant place. Although each created monad reflects the whole univerfe, that monad which is the animating principle of any body, affects that body more diftinctly than all others. As the whole body reflects the whole univerfe by the connection of all matter *in pleno*, fo alfo the foul reflects the whole univerfe, while it reflects that organized body, by which it is in a peculiar manner perceived, and with which it feems a living animal. Since matter is not only infinitely divifible, but is actually divided without limit, every portion of matter may be conceived to be a world of living creatures; and every part of a living body to be itfelf full of all other living bodies. All bodies are like rivers, perpetually flowing; fome parts entering, and others paffing away. The foul changes its body, not inftantaneoufly, but by degrees, fo that, ftrictly fpeaking, there is no fuch thing as death, or a ftate in which the foul is feparated from the body. In conception, no new animal is produced; but a pre-exifting animal is difpofed to a transformation, by which it paffes into another fpecies. In death, though the machine in part perifhes, the animal itfelf remains indeftructible.

From

From this concise statement of Leibnitz's system, as it respects monads, it will be easily perceived, that his monads approach nearer to the permanent intelligent natures, called by Pythagoras numbers, and by Plato ideas, than to the solid and indivisible atoms of Epicurus. Brucker's Philos. by Enfield, vol. ii. See LEIBNITZIAN *Philosophy*.

MONADELPHIA, in *Botany*, from μονος, *one*, and αδελφος, *a brother*, the 16th class of the Linnæan artificial, or sexual, system, consisting of plants whose filaments are united into one parcel, or set. This union is more or less complete. In the Mallow tribe, the combined filaments make a long tube, crowned at its summit by the anthers, which, from its resemblance to a column, has obtained the name of *columniferæ* for such flowers. In the Geranium family the union is much more slight; while in some genera, as *Oxalis*, it is but partial, or confined to certain species only. The late professor Cavanilles, of Madrid, undertook an illustration of the class *Monadelphia*, in several quarto dissertations, with plates, which make all together two rather thick volumes. In this work he has referred to the class in question a vast number of genera, never before suspected to belong to it, and which unquestionably want its true character. This character consists in an actual union, or immediate coalescence, of the filaments themselves into one body; whereas many of the plants considered by Cavanilles as monadelphous, are so merely through the medium of a tubular nectary, or of some other body, which is no part of the stamens. This is totally inadmissible, for we might just as well refer to this class, every plant whose filaments are connected by insertion into a corolla, or calyx, of one piece.

The class *Monadelphia* is not in itself a natural one, though it embraces some tribes that are natural combinations, as the *Columniferæ* and *Gerania*. Its orders are distinguished by the number of stamens, easily determined at their upper part, bearing the anthers, where they are always, for a considerable distance, separate and distinct. These orders are eight, *Triandria, Pentandria, Heptandria, Octandria, Decandria, Endecandria, Dodecandria*, and *Polyandria*; of which the last, comprising the *Columniferæ*, and some other noble plants, is the most numerous and important.

MONADELPHIA is also the name of an order of the 21st and 22d classes (*Monoecia* and *Dioecia*) of the Linnæan system, founded on the same character as the class so denominated. This order in the 21st class is chiefly formed of the Fir, or coniferous, tribe, and of some of the natural order of *Euphorbiæ* of Jussieu; in the 22d also it contains some of the allies of the Fir, with a very few genera besides. Professor Willdenow has removed the Gourd or Cucumber tribe to the *Monoecia Monadelphia*, justly perceiving that they were inaccurately referred to *Monadelphia Syngenesia* by Linnæus; an order which, as far as is hitherto known, has no existence in nature. Their anthers in fact are quite distinct, their filaments only being more or less combined. But this combination is not into one set, except perhaps in *Sicyos* and *Sechium*. The rest of this tribe are by no means monadelphous, but polyadelphous, their five stamens being united by their filaments into three sets. See MOMORDICA.

MONADNOCK, GREAT, in *Geography*, a mountain of America, in Cheshire county, New Hampshire, between the towns of Jeffrey and Dublin. The foot of the hill is 1395 feet, and its summit 3254 feet, above the level of the sea. Its base is five miles in diameter from N. to S., and three from E. to W. On the sides are some appearances of subterraneous fires.

MONADNOCK, *Upper Great*, a high mountain in Canaan, in the N.E. corner of the state of Vermont.

MONAGHAN, a county of Ireland, in the province of Ulster. It is rather of an oblong form, having its greatest extent from north to south, and being very narrow, except in one part, where it stretches between the counties of Fermanagh and Cavan, which form its western boundary. On the north it runs into the county of Tyrone in an angular direction, being separated from it on the north-east by the river Blackwater. The county of Armagh lies on the east of it, that of Louth on the south-east, and that of Meath on the south. The length of this county is 30 miles (38 English) from north to south; its greatest breadth is 19 miles (24 English), but in most parts it does not exceed 10, and is not always so much. The area is 179,600 Irish plantation equal to 288,500 English acres; and in square miles 280 Irish or 450 English. This is the statement of Dr. Beaufort and sir Charles Coote. Mr. Wakefield, for what reason he does not state, says the area is 509 English miles. The whole is divided into 21 parishes, of which 20 had churches when Dr. Beaufort published, all in the diocese of Clogher. The population is stated by Dr. Beaufort at 118,000 for 21,523 houses; but the general increase since the publication of his work is sufficient ground for considering it too low an estimate.

Monaghan has a large proportion of bog, and a great number of small lakes, which, together with its being exposed to the north-westerly winds, render it very damp, though it is far from being unwholesome. On the north-west the Sliebh-Baught mountains divide it from Tyrone; and on the east the Fews mountains are the boundary. In most parts of the county the surface is hilly, but no part is inaccessible to the plough. The turf bogs, supplying abundance of fuel, are of great value, and have been reckoned one cause of its great population, in which it is inferior to no county in Ireland, Dublin and Armagh alone excepted. The soil is in general deep clay, which is particularly favourable for flax, and this is the principal crop. In 1809 three thousand two hundred acres were sown with flax, a greater number in proportion to the extent than in any county except Armagh. Potatoes and oats are successfully cultivated, but there is very little wheat; and the small farms into which the land is divided do not answer for grazing or dairy husbandry. The lower classes are sensible of the value of vegetables, which are raised very abundantly in their little gardens; and with similar encouragement to that given by lord Hardwicke on his estate in Cambridgeshire, these gardens would contribute in a still greater degree to the comfort of the proprietors. The linen manufacture is the great object of the people, and is productive of its usual happy effects, though it is not favourable to improved agriculture. The Slieb-Baught mountains, which extend into this county from Tyrone, form an uninterrupted ridge of high land, the highest part of which is called Cairnmore. These have, in general, neither a fruitful soil, nor any natural beauties to recommend them, being an uninteresting waste, and almost always wet and moory. There are parts, however, which have beds of the richest limestone, and abundance of marle, particularly on the eastern side of Cairnmore. This mountain is famous for its millstone quarry. Those most valued consist of a red and very hard grit or sandstone, the grain of which is close. There is also a soft whitish sandstone, which is more easily procured, but which soon wastes away. In this neighbourhood is also a fine kind of potters' clay, which is carried to the pottery at Dundalk, and is used in making the best thin glazed ware. Indications of coal have also been observed here, and in other parts of the county. Crieve, which is south of the town of Ballibay, is the highest ground in Monaghan. The stone here is of a very hard

hard quality, of a colour between blue and dark green, and is found to anſwer very well for building. It is called *whinſtone*, and ſeems to be a kind of greenſtone. Crieve abounds with lead ore of the richeſt quality. On the ſummit of this mountain is a lake covering about fifty acres, which is very deep, and is principally ſupplied from ſprings. This lake ſerves as a reſervoir for ſupplying a number of bleach-mills, fourteen of them being worked by the ſtream flowing from it. The conſequence of theſe eſtabliſhments has been the reclaiming of a conſiderable part of the mountain, notwithſtanding the badneſs of the ſoil; ſo that what was regarded a few years ago as a waſte with nothing to recommend it, has, in conſequence of the application of a ſtream of water to the prevailing manufacture, become a moſt thriving and valuable diſtrict. It has been already mentioned, that Monaghan abounds with ſmall lakes which might be turned to the ſupply of a canal extending through it from lough Neagh to lough Erne, which ſeems to be practicable without very great expence, ſhould the improvement of the country render it deſirable. The number of theſe lakes is 184, of which 30 are conſiderable ſheets of water. Lough Barrac, near Caſtle Blayney, and the lake of Kilcrow at Coote Hill, principally deſerve notice for their extent and beauty. The rivers are numerous, but inconſiderable. Of Monaghan, the county town, an account will be given in the next article. Clones, Carrickmacroſs, Caſtle Blayney, and Ballibay, have been noticed in preceding volumes under their reſpective heads. As none of them are boroughs ſince the Union, Monaghan is repreſented in parliament by only two members, who are, according to Mr. Wakefield, returned by no individual prevailing intereſt.

In the hiſtory of Ireland we do not find any matter of moment relating to this county until the reign of James I., when 500,000 acres in Ulſter were eſcheated to the crown under the charge of the proprietors being diſaffected to the king's government, which forfeiture included almoſt the whole of Monaghan. A great part of theſe lands was ſoon after aſſigned to Britiſh adventurers, moſtly Scotch; but conſiderable eſtates were left, according to ſir John Davis's ſtatement, to ſeveral of the name of M'Mahon, which had been the prevailing family in it. Theſe were probably forfeited at a ſubſequent period, as the name of M'Mahon does not occur in the liſt of the preſent proprietors given by ſir Charles Coote. "The rent rolls of large eſtates," ſays the writer laſt named, "will be found from near 20,000*l.* to 1,000*l. per annum*, and a very conſiderable part is held in grants from 20*l.* to 500*l. per annum*. The large eſtates are in no inſtance reſided on by the immediate proprietors, but the leſſer ones are almoſt uniformly otherwiſe, and are held in grants from the crown, ſince the Scotch colony was introduced here; and alſo a conſiderable ſhare of theſe lands comprehended gifts to Cromwell's ſoldiers, many of whoſe poſterity now enjoy ſo ſmall a tract, as does not yield above 20*l.* annual income. I ſuppoſe taking the large farms in Monaghan they would not average 25 acres; nor could the ſmall ones, which are far more numerous, average ſix acres, ſo that ten may be the mean rate of the whole county." "The largeſt eſtates," according to Mr. Wakefield, "exhibit the moſt wretched cultivation; fields without hedge-rows, and encloſed only by earthen banks or dykes; land running to waſte, which, with great truth, may be compared to its inhabitants, that is, loſing its ſtrength for want of proper nouriſhment, and exiſting in a ſtate of the utmoſt poverty." It would be eaſy to enlarge upon the evils ariſing from non-reſident landlords, rack-rents paid to middle men, and a conſequent wretched ſyſtem of agriculture; but to do ſo in this place would not be likely to contribute to amendment, and the remarks would not belong to this more than to many other counties. Beaufort's Memoir. Sir C. Coote's Statiſtical Survey. Wakefield's Account of Ireland.

Monaghan, a market and poſt-town of Ireland, and the ſhire-town of the county of Monaghan, deſcribed in the preceding article. Before the Union it was a borough, but is not now repreſented. It is 62 miles N.N.W. from Dublin. N. lat. 54° 16'. W. long. 6° 49'.

MONAH, a town of Hindooſtan, in Baramaul; eight miles N. of Namacul.

MONAHAN, a townſhip of America, in York county, Pennſylvania.

MONAINCHA, in *Eccleſiaſtical Antiquities*, the name of a celebrated old monaſtery in Ireland, which belonged to the Culdees, and is mentioned by Cambrenſis. It is ſituated in the bog of Monela, in the county of Tipperary; three miles S.E. from Roſcrea. Archdall. Ledwich.

MONAMBASCHAGATT, a town of Africa, on the river Camarones.

MONANDRIA, in *Botany*, from μονος, *one*, and ανηρ, *a man*, the firſt claſs of the Linnæan ſexual, or artificial, ſyſtem, characterized by having one ſtamen only, in the ſame flower with the piſtil. It conſiſts of two orders, diſtinguiſhed by the number of their ſtyles, or ſeſſile ſtigmas; like all the orders of the firſt 13 claſſes of this ſyſtem. Some few ſpecies of *Valeriana*, a naturally triandrous genus, are monandrous.

The character of this claſs is in general eaſy and obvious, but a difference of opinion exiſts among botaniſts, concerning ſome genera which Linnæus has referred to it. Theſe are of the natural order of *Scitamineæ*, in ſeveral of which order the two lobes of the anther are ſeparated by the breadth of the filament, which is in them unuſually great. But that theſe two lobes do really conſtitute one anther only, is evident from other genera of the ſame natural order, in which, the filament being but of the ordinary ſlender dimenſions, the two lobes are brought cloſely together. There are other inſtances of a ſimilar diſtance between the two lobes of an anther, as in *Berberis*.

Monandria is likewiſe the name of an order of the claſs *Gynandria*, as well as of the *Monoecia* and *Dioecia*. Reſpecting the two laſt, every body is agreed, but the firſt has been eſtabliſhed ſince the time of Linnæus, and conſiſts of all the known *Orchideæ*, except *Cypripedium*, which that great botaniſt conſidered as having two anthers, but which prove, on a correct inveſtigation, and eſpecially by the analogy of the *Scitamineæ*, to have really but one. See Orchideæ and Scitamineæ.

Some ſpecies of *Salix*, conſidered as monandrous, are perhaps more truly monadelphous, their anther being certainly double, and their filaments two, united into one from the bottom to the very ſummit. In other ſpecies this union is but partial, and theſe are univerſally deemed monadelphous.

MONANTHUEIL, Henry de, in *Biography*, or, when latinized, *Monantholius*, a French phyſician and mathematician, was born of a noble family, poſſeſſed of an eſtate of the ſame name, in the Vermandois, about the year 1536. His birth place was Rheims; but he received his education in the college of Preſla, at Paris, under the direction of the celebrated Ramus, whoſe doctrines he afterwards defended. He then transferred his ſtudies to the college royal, where he applied with ardour both to mathematics and medicine, and received the degree of doctor in the latter ſcience. He held the office of dean of the faculty of medicine for two ſucceſſive years, 1578 and 1579. His mathematical acquirements had obtained for him the appointment of profeſſor in 1576, which

which he fulfilled with so much distinction, as to gain the honour of numbering among his auditors the celebrated James Augustus de Thou, the learned Peter de Lamoignon, and other eminent characters. He continued to perform the duties of this professorship with undiminished zeal and reputation, for a period of thirty years; while at the same time he did not neglect those of his medical office. He was extremely active in maintaining the privileges of the faculty, and successfully exposed the impositions of a noted empiric of his day, named La Riviere, who was exiled from Paris by an arrêt of parliament. He was on terms of intimate friendship with William du Vair, keeper of the seals; and was the Musæus, on whom that gentleman bestowed so high an eulogium in his discourse "On Constancy." He was distinguished by his steady loyalty during the trouble of the *league*, and pronounced the first public panegyric on king Henry IV., when his majesty obtained the possession of Paris from the hands of that faction. He died in the year 1606, highly respected for every quality that could adorn the man and the scholar. He was author of the following works: "Liber de Angulo Contactus, adversus Jacobum Peletarium," 1581;—"Oratio, quale esse deberet Collegium Professorum Regiorum," 1595;—"Ludus Jatro-mathematicus, Musis factus," 1597;—"Commentarii in Librum Aristotelis de Mechanicis," with the Greek text, and a new Latin version, 1599;—"De Puncto, primo Geometriæ principio, Liber," 1600;—"Problematis omnium quæ à 1200 annis inventa sunt nobilissimi Demonstratio," 1600. And he left in an unfinished state a large mathematical work, entitled "Hepatecnon Mathematicum," on which he had been long occupied. Gen. Biog. Eloy Dict. Hist.

MONARCHICI, in *Church History*, heretics towards the end of the second century, who allowed but one person in the godhead, and maintained that the father, the creator of all things, had united himself to the human nature of Christ; whence they were called Monarchians; and they also taught that the father was crucified; on this account they were denominated Patripassians.

MONARCHY, μοναρχια, a large state governed by one; or a state where the supreme power is lodged in the hands of a single person.

The word comes from the Greek μοναρχης, *one who governs alone*; formed of μονος, *solus*, and αρχη, *imperium, government*.

Of the three forms of government, *viz.* democracy, aristocracy, and monarchy, the last is the most powerful, all the sinews of government being knit together, and united in the hand of the prince; but then there is imminent danger of his employing that strength to improvident or oppressive purposes. As a democracy is the best calculated to direct the end of a law, and an aristocracy to invent the means by which that end shall be obtained, a monarchy is most fit for carrying those means into execution.

Honour, says Montesquieu, which aspires to preferments and distinguishing titles, is the prevailing principle in monarchies; this sets all the parts of the body politic in motion; by its very action it connects them, and thus each individual advances the public good, while he only thinks of promoting his own particular interest; this principle gives life, not only to the whole body politic, but to the laws, and even to the virtues themselves. This principle is altogether unknown in despotic governments; of which fear is the principle.

As honour is the principle of a monarchical government, systems of education and of legislation should be formed and conducted with a constant regard to this principle. The nobility should be rendered respectable and hereditary, and their lands should have privileges annexed to them as well as their persons. The laws should also favour all kinds of commerce, consistent with the constitution of the government, that the subjects may be able, without ruining themselves, to satisfy the continual cravings of the prince and his court. Some fixed regulation should also be established, that the manner of collecting the taxes may not be more burdensome than the taxes themselves.

Monarchy has a great advantage over a despotic government. As it naturally requires there should be several orders belonging to the constitution under the prince, the state is more fixed, the constitution more steady, and the person of him that governs more secure. We may also add, that as people who live under a good government, are happier than those who, without rule or leaders, wander about the forests; so monarchs who live under the fundamental laws of their country, are far happier than despotic princes, who have nothing to regulate either their own, or their subjects' hearts. In monarchies, where honour alone predominates, the prince's rewards would consist only of marks of distinction, if the distinctions established by honour were not annexed to a luxury which is necessarily attended with wants; the prince therefore is obliged to confer honours that lead to wealth; and it is a general rule, that great rewards, in monarchies and republics, are a sign of their decline; because they are a proof of their principles being corrupted, and that the idea of honour has no longer the same force in monarchy, nor the title of citizen the same force in a republic. The very worst Roman emperors were those who were most profuse in their largesses, *viz.* Caligula, Claudius, Nero, Otho, Vitellius, Commodus, Heliogabalus, and Caracalla. The best, such as Augustus, Vespasian, Antoninus Pius, Marcus Aurelius, and Pertinax, were economists. Under good emperors the state resumed its principles; all other treasures were supplied by that of honour. In a republic presents are odious, because virtue does not need them. In monarchies honour is a much stronger incentive than presents. But in a despotic government, where there is neither honour nor virtue, people cannot be determined to act but through hopes of the conveniences of life. In monarchical governments, Montesquieu is of opinion, that the laws ought not to oblige a subject to accept of a public employment; nor should a subject be obliged to accept of a post in the army inferior to what he held before, because honour, true or false, will never bear with what it calls degrading itself; nor should civil and military employments be conferred on the same person; nor is venality of public employments improper, as he thinks, in monarchies. He adds, that in monarchies there should be no censors, because being founded on honour, it is in the nature of honour to have the whole universe for a censor. In monarchies, the administration of justice, which decides not only in regard to life and property, but likewise to honour, demands very scrupulous inquiries. In monarchies, it is a great inconvenience for the ministers of the prince to be judges. Our author thinks, that luxury is extremely proper for monarchies, and that under this government there ought to be no sumptuary laws. Republics, he says, end with luxury, and monarchies with poverty. As democracies are destroyed when the people despoil the senate, magistrates, and judges of their functions; so monarchies are corrupted when the prince insensibly deprives societies of their prerogatives, or cities of their privileges. In the first case the multitude usurp a despotic power; in the second it is usurped by a single person. Monarchy is destroyed, when a prince thinks he shews a greater exertion of power in changing, than in conforming to the uses of things; when he deprives some of his

his subjects of their hereditary employments, to bestow them arbitrarily upon others, and when he is fonder of being guided by his fancy than by his judgment. It is destroyed, when the prince, directing every thing to himself, calls the state to his capital, the capital to his court, and the court to his own person. Monarchy is destroyed, in fine, when the prince mistakes his authority, his situation, and the love of his people; and when he is not fully persuaded, that a monarch ought to think himself secure, as a despotic prince ought to think himself in danger. Montesq. Sp. of Laws, vol. i. passim.

The most ancient monarchy was that of the Assyrians, which was founded soon after the deluge, in the year 2059 B.C. We usually reckon four grand or universal monarchies; the Assyrian, Persian, Grecian, and Roman: though St. Augustine makes them but two, *viz.* those of Babylon and Rome. Belus is placed at the head of the series of Assyrian kings who reigned at Babylon, and is by profane authors esteemed the founder of it, and by some the same whom the scriptures call Nimrod. The principal Assyrian kings after Belus were Ninus, who built Nineveh, and removed the seat of empire to it; Semiramis, who, disguising her sex, took possession of the kingdom instead of her son, and was killed and succeeded by her son Ninyas; and Sardanapalus, the last of the Assyrian monarchs, and more effeminate than a woman. With him terminated the ancient monarchy of Assyria, in the year 820 B.C. After his death, the Assyrian empire was split into three separate kingdoms; *viz.* the Median, Assyrian, and Babylonian. The first king or prefect of the Median kingdom was Arbaces; and this kingdom lasted till the time of Astyages, who was subdued and divested of his kingdom by Cyrus. The first king of the new Assyrian kingdom was Phul, who began his reign in the year 777 B.C., and this kingdom was united to that of Babylon under Assaradinus, 680 B.C. The Babylonian kingdom commenced under Nabonassar, 747 B.C., and after being united to that of Assyria, was again separated, 667 B.C., Saosduchinus being its first king, and Ninus II. king of Assyria. These monarchies continued separate until the year 606 B.C., when Assyria was united to Media. The Babylonian kingdom terminated by the conquest of Cyrus, 538 B.C. In the time of Cyrus, there arose a new and second monarchy, called the Persian; which stood upwards of two hundred years, from Cyrus, whose reign began 559 B.C., to Darius Codomannus, who was conquered by Alexander, 331 B.C., and the empire translated to the Greeks. The first monarch was Cyrus, founder of the empire; the second Cambyses, the son of Cyrus. 3. Smerdis. 4. Darius, the son of Hystaspes, who began his reign 521 B.C. 5. Xerxes, who succeeded Darius, 485 B.C. 6. Artaxerxes Longimanus, who commenced his reign 464 B.C. 7. Xerxes II., who began his reign 425 B.C. 8. Ochus, or Darius, called Nothus, 424 B.C. 9. Artaxerxes Mnemon, 404 B.C. 10. Artaxerxes Ochus, 358 B.C. 11. Arses, 337 B.C. 12. Darius Codomannus, 335 B.C., who was defeated by Alexander the Great, and deprived of his kingdom and life about 331 B.C.; the dominion of Persia after his death was translated to the Greeks. The third monarchy was the Grecian. As Alexander when he died did not declare who should succeed him, there started up as many kings as there were commanders. At first they governed the provinces, that were divided among them, under the title of viceroys; but when the family of Alexander the Great was extinct, they took upon them the name of kings. Hence, in process of time, the whole empire of Alexander produced four distinct kingdoms; *viz.* 1. The Macedonian, the kings of which, after Alexander, were Philip, called Aridæus, 323 B.C., Cassander, 316 B.C., Antipater and Alexander, 298 B.C., Demetrius Poliorcetes, 294 B.C., Pyrrhus, 287 B.C., Lysimachus, 286 B.C., Ptolemy, called Ceraunus, 280 B.C., Meleager, 279 B.C., Antipater the Etesian, 278 B.C., Antigonus Gonatas, 277 B.C., Demetrius, 243 B.C., Antigonus Doson, 232 B.C., Philip, 221 B.C., and Perseus, 179 B.C., under whom the Macedonian kingdom was reduced to the form of a Roman province. 2. The Asiatic kingdom, which, upon the death of Alexander, fell to Antigonus, 311 B.C., comprehending that country now called Natolia, together with some other regions, beyond Mount Taurus. From this kingdom proceeded three lesser ones; *viz.* that of Pergamus, whose first king was Philetærus the Eunuch, 283 B.C., and whose last king, Attalus, called Philometor, in the year 132 B.C., appointed the Roman people to be his heir: Pontus, reduced by the Romans into the form of a province, when they had subdued the last king, Mithridates; and the Syrian. 3. The Syrian, to which that of Babylon was united, of whose twenty-two kings the most celebrated were Seleucus Nicator, founder of the kingdom, 312 B.C., Antiochus Deus, 261 B.C., Antiochus the Great, 223 B.C., Antiochus Epiphanes, 175 B.C., Tigranes, 83 B.C., and Antiochus Asiaticus, 69 B.C., who was conquered by the Romans under Pompey; and Syria was reduced into the form of a Roman province, 65 B.C. 4. The Egyptian, which was formed by the Greeks in Egypt, and flourished near two hundred and forty years under twelve kings; the principal of whom were Ptolemy Lagus, its founder, 323 B.C., Ptolemy Philadelphus, 284 B.C. founder of the Alexandrian library; and queen Cleopatra, who was overcome by Augustus; in consequence of which Egypt was added to the dominion of the Romans, 30 B.C. The fourth monarchy was the Roman, which lasted two hundred and forty-four years, from the building of the city, until the time when the royal power was abrogated. The kings of Rome were Romulus its founder, Numa Pompilius, Tullus Hostilius, Ancus Martius, Tarquinius Priscus, Servius Tullius, and Tarquin the Proud, who was banished, and with whom terminated the regal power. Holberg's Introd. to Univ. Hist. by Dr. Sharp, p. 85, &c.

There seems, in reality, no necessity to make the Medes, Persians, and Greeks, succeed to the whole power of the Assyrians, to multiply the number of the monarchies: it was the same empire still, and the several changes that happened in it, did not constitute different monarchies. Thus the Roman empire was successively governed by princes of different nations, yet without any new monarchy being formed thereby. Rome, therefore, may be said to have immediately succeeded Babylon in the empire of the world. See Empire.

Of monarchies some are *absolute* and *despotic*, where the will of the monarch is uncontrollable, as Denmark, &c.; others are *limited*, where the prince's authority is restrained by laws, and part of the supreme power lodged in other hands; as in England. See Government.

Some monarchies, again, are *hereditary*, where the succession devolves immediately from father to son; and others are *elective*, where, on the death of the monarch, his successor is appointed by election.

According to Hobbes, monarchy, as well as aristocracy, derives all its authority from the people, who transfer all their right, *v. gr.* the supreme power, by a plurality of suffrages, &c. to some one person called a monarch; so that whatever the people could have done before this translation, may be now rightfully done by him to whom the

the tranſlation is made. This done, the people are no longer to be looked upon as a body, but a diſſolved multitude; becauſe they were only one by virtue of the ſupreme power, which they have now transferred to another.

Nor can the monarch, according to this author, oblige himſelf by any covenants, to any perſon, for the authority he has received; becauſe he receives the power from the people, which, as ſoon as that is done, ceaſes to be a body; and the body ceaſing, the obligation to the body ceaſes of courſe. The people, therefore, are obliged to pay obedience to the monarch, by virtue of thoſe covenants, whereby they mutually oblige themſelves to what the people, as a body, enjoin to be done.

He argues, farther, that as a monarch cannot be obliged by any covenants; ſo neither can he do any injury to his ſubjects; an injury being nothing elſe but a breach of covenant; and where there is no covenant, there can be no breach of one. De Cive, c. 8. See HOBBISM.

Fifth-MONARCHY *Men*, in the *Eccleſiaſtical Hiſtory of England*, were a ſet of wrong-headed and turbulent enthuſiaſts who roſe in the time of Cromwell, and who expected Chriſt's ſudden appearance upon earth to eſtabliſh a new kingdom: and, acting in conſequence of this illuſion, aimed at the ſubverſion of all human government. Burnet's Hiſt. of his Own Times, vol. i. p. 67.

MONARDA, in *Botany*, named in honour of Nicholas Monardes, a Spaniſh phyſician and botaniſt who lived at Seville towards the cloſe of the ſixteenth century, and who publiſhed various treatiſes relating to the natural productions, and eſpecially to the *Materia Medica*, of the new world.—Linn. Gen. 16. Schreb. 22. Willd. Sp. Pl. v. 1. 124. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 50. Vahl. Enum. v. 1. 217. Michaux. Boreal-Amer. v. 1. 16. Juſſ. 111. Lamarck Illuſtr. t. 19. Gærtn. t. 66.—Claſs and order, *Diandria Monogynia.* Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, cylindrical, ſtriated, permanent, with a five-toothed, equal mouth. *Cor.* unequal; tube cylindrical, longer than the calyx; limb ringent: upper lip ſtraight, narrow, linear, undivided; lower reflexed, broader, cloven into three ſegments, of which the middle one is longer, narrower, and emarginate; its ſides obtuſe. *Stam.* Filaments two, briſtle-ſhaped, as long as the upper lip, by which they are embraced; anthers compreſſed, truncated at the top, convex and ſtraight at the lower part. *Piſt.* Germen ſuperior, four-cleft; ſtyle thread-ſhaped, parallel to the ſtamens; ſtigma cloven, acute. *Peric.* none. *Seeds* four, roundiſh, lying at the bottom of the calyx.

Obſ. *M. didyma* has four ſtamens, two of which are abortive.

Eſſ. Ch. Corolla unequal, its upper lip linear, and incloſing the filament. Seeds four.

1. M. *fiſtuloſa.* Purple or Crimſon Canada Monarda. Linn. Sp. Pl. 32. J. Miller. Illuſtr. t. 3. (M. fiſtuloſa, *var;* Curt. Mag. t. 145.)—Leaves oblong-lanceolate, pointed, hairy, flat. Stems obtuſely angular.—Native of Canada as well as other parts of North America, cultivated by Mr. John Tradeſcant in 1656. It flowers from June to Auguſt.—*Root* perennial, ſtrongly fibrous and ſpreading. *Stems* nearly three feet high, obtuſely angular, hairy, branched at the upper part. *Leaves* oppoſite, on ſhort ſtalks, broad at the baſe, but ſharply pointed at the end, hairy and toothed. *Flowers* in one or two terminal, denſe whorls, of a beautiful deep crimſon colour.—The whole herb is remarkable for its fragrance as well as beauty, and is not unfrequently cultivated in our gardens. The variety figured by Curtis, and quoted above, is larger and more ſhowy than the original ſpecies, its bloſſoms far ſurpaſſing that in ſize and brilliancy of colour. The floral leaves alſo are richly tinted with lilac or purple.—Upon comparing Curtis's figure with the Linnæan Herbarium, it appears that this variety of *fiſtuloſa* is what Linnæus has called *M. mollis* in the third volume of the *Amœnitates Academicæ*, p. 399.—It may be propagated by parting its roots.

2. M. *oblongata.* Long-leaved Monarda. Willd. n. 2. Ait. Hort. Kew. ed. 2. v. 1. 51.—Leaves oblong-lanceolate, rounded and ſomewhat contracted at the baſe, hairy, flat.—Native of North America, and cultivated in 1761, by Mr. James Gordon. It flowers from July to September.—There is no figure of this ſpecies, but, from a ſpecimen in Dr. Smith's herbarium, we find that it chiefly differs from the preceding in having its *leaves* more oblong, and more attenuated, though not actually tapering, at the baſe; they are alſo more hairy on the under ſide. The *calyx* is ſhorter and more hairy at the margin. The *flowers* alſo are ſmaller.

3. M. *didyma.* Scarlet Monarda, or Oſwego-Tea. Linn. Sp. Pl. 33. Curt. Mag. t. 546. (M. coccinea; Michaux. Boreal-Amer. v. 1. 16.)—Leaves ovate, ſmooth. Whorls of flowers capitate, with two imperfect, additional ſtamens. Stem acutely angular.—Native of rills on the mountains of North America; introduced into this country by Peter Collinſon, before 1752. It flowers from June to Auguſt.—*Root* perennial. *Stems* about two feet high, ſquare, acutely angular, branched ſo as to become buſhy towards the top. *Leaves* oppoſite, on ſhort ſtalks, toothed and fringed at the edge, when bruiſed, emitting a grateful, refreſhing ſmell, which, independently of the beauty of the plant, would entitle it to a place in every garden. *Flowers* much like thoſe of *M. fiſtuloſa* in habit, but larger, and of a rich ſcarlet hue; moſt of them furniſhed with two additional abortive ſtamens, whence the ſpecific name.—This increaſes greatly by throwing out radical ſhoots, which may be tranſplanted.

4. M. *rugoſa.* White Monarda. Willd. n. 4. Ait. Hort. Kew. ed. 2. v. 1. 51.—Leaves ovato-lanceolate, heart-ſhaped, ſmooth, rugoſe.—Native of North America; cultivated in 1761, by Mr. James Gordon; flowering from July to September.—This ſpecies is adopted by Vahl and Martyn from Aiton, but as we are unacquainted with any ſpecimen or figure, we can only give profeſſor Willdenow's deſcription, who ſays that it is very nearly allied to the following ſpecies, *M. clinopodia*, but that its *leaves* are longer, ſmooth, and ſomewhat rugoſe like thoſe of many ſpecies of *Salvia*. The *flowers* alſo are white.

5. M. *clinopodia.* Wild Baſil-leaved Monarda. Linn. Sp. Pl. 32.—Leaves ovato-lanceolate, ſmooth, rounded and unequal at the baſe.—Native of Virginia; cultivated by Mr. William Malcolm in 1771. It flowers in July.—*Root* creeping. *Stems* about two feet high, ſquare, rather acutely angular, branched. *Leaves* oppoſite, remarkably ſmooth, attenuated, remotely ſerrated; the floral ones narrower, and coloured at the baſe. *Flowers* capitate, terminal, of a pale colour.—The ſpecific name originated from a ſtriking reſemblance in the leaves to thoſe of *Clinopodium incanum*, and was originally written by Linnæus, on the ſpecimen in his herbarium, *clinopodifolia*.

6. M. *punctata.* Spotted Monarda. Linn. Sp. Pl. 32. Andr. Repoſ. t. 546. Sm. Inſects of Georgia, t. 24. (M. lutea; Michaux Boreal-Amer. v. 1. 16.)—Flowers in whorls. Corolla ſpotted. Bracteas large and coloured.—Native of North America; cultivated here in 1714, by Mr. Thomas Fairchild.

Fairchild.—*Root* biennial. *Stems* erect, nearly two feet high, branched, jointed. *Leaves* in ftalks, lanceolate, in clufters at each joint, ferrated from the middle to the end, fmooth, veined. *Flowers* axillary, in denfe whorls, yellow, fpotted with purple, accompanied by very handfome, crimfon *bracteas*. Michaux has changed the fpecific name to *lutea*, becaufe he obferves, the *corolla* in every fpecies of *Monarda* is fpotted. We cannot however accede to this change, as in our prefent plant, the fpots on the corolla are fo infinitely more apparent than in any other, as to render the name fufficiently defcriptive.

7. M. *allophylla*. Various-leaved Monarda. Vahl. Enum. v. 1. 219. Michaux. Boreal-Amer. v. 1. 16.—Leaves oblong, ferrated. Calyx bearded at the border. Flowers capitate, terminal.—Found by Michaux in North America, from whom and Vahl all that we know of it is collected. The former fays, that the fhape, ferratures, and pubefcence of its *leaves* are fo various as to induce a fuppofition that its varieties may conftitute different fpecies. *Flowers* flefh-coloured.

8. M. *ciliata*. Virginian ciliated Monarda. Linn. Sp. Pl. 33. (Clinopodium anguftifolium non ramofum, flore cæruleo: labio trifido, atropurpureis maculis ornato; Pluk. Alm. t. 164. f. 3.)—Leaves oblong or oval, gradually pointed. Flowers capitate, whorled. Bracteas ciliated.—Native of Virginia and Carolina. Introduced at Kew by Mr. Francis Maffon in 1798. It flowers in July. —*Root* creeping. *Stems* a foot or more in height, diftantly jointed, hairy, efpecially at the upper part. *Lower leaves* on ftalks, roundifh, an inch long, notched; upper ones feffile, narrower. *Flowers* capitate, in whorls, large, blue, elegantly marked, with dark purple fpots. The habit and appearance of this fpecies are different to all the reft, and it has the fmell of Mint.

Monarda, in *Gardening*, contains plants of the fibrous-rooted, herbaceous, flowery, biennial, and perennial kinds, of which the fpecies cultivated are: the purple monarda (M. fiftulofa); the long-leaved monarda (M. oblongata); the fcarlet monarda, or Ofwego tea (M. didyma); the white monarda (M. rugofa); and the fpotted monarda (M. punctata).

Method of Culture.—All thefe plants may be increafed by parting the roots, and fome of them by flips and cuttings as well as feeds. But as the firft fort does not increafe faft by the roots, the feeds may be fown in the autumn on a bed of good earth, and in the following fummer the plants be removed into nurfery rows half a foot apart, in a rather fhady fituation, and in the beginning of the following autumn fet out where they are to remain and flower. They fucceed beft in a foft loamy foil not too much expofed.

The roots fhould be divided either in the autumn or very early fpring, but the former is the better feafon, being afterwards either planted out in rows till they are ftrong, or, when ftrong, at once where they are to remain. And ftrong flips or cuttings of the branches may be taken off in the beginning of fummer, and planted out in a fhady border, due fhade and water being given till well rooted, when in the autumn they may be removed to where they are to remain.

The third fpecies fucceeds beft in a light foil in an eaftern afpect.

Thefe plants all afford ornament in the borders and clumps of pleafure-grounds, &c.

MONARDES, Nicholas, in *Biography*, a Spanifh phyfician, was born at Seville in the early part of the fixteenth century. He received his education at the univerfity of Alcala de Henarez, and fettled in the practice of his profeffion in his native city. Little is recorded refpecting his life, which terminated at the fame place in the year 1578. He was confiderably diftinguifhed, however, by his writings, the firft of which related to a controverted queftion, and was entitled, "De fecanda vena in Pleuritide inter Græcos et Arabes concordia," Hifpal. 1539. His next was a tract, "De Rofa et partibus ejus; de fucci Rofarum temperatura, &c."—But his reputation was chiefly extended by his work, in the Spanifh language, concerning the medicinal fubftances imported from the new world, entitled, "Dos Libros de las cofas que fe traen de las Indias Occidentales, que firven al ufo de Medicina," Sevilla 1565. It was reprinted in 1569 and 1580, and to the latter edition a third book was added. Charles l'Eclufe, or Clufius, tranflated this work into Latin, with the title of "Simplicium Medicamentorum ex novo orbe delatorum, quorum in Medicina ufus eft, Hiftoria," Antw. 1574, and improved it by his annotations, and by the addition of figures. This work was alfo tranflated into Italian and French. The botanift will feek in vain for accuracy in his defcriptions, but the work was ufeful, by exciting the public attention to medicines heretofore little known. Monardes alfo publifhed three works in Spanifh, which were tranflated into Latin by l'Eclufe, with the title of "Nicolai Monardi Libri tres, magna Medicinæ fecreta et varia Experimenta continentes," Lugd. 1601. The firft of thefe relates to the lapis bezoardicus; the fecond, to the ufe and properties of fteel, which he was the firft after Rhazes to recommend as a deobftruent, according to Dr. Freind; and the third, to the efficacy of fnow. His name is perpetuated by the botanical genus *Monarda*, in the clafs diandria of Linnæus. Eloy Dict. Hift. Gen. Biog.

MONAS, in *Natural Hiftory*, a genus of infects of the order Infuforia. The generic character is, worm invifible to the naked eye, moft fimple, pellucid, refembling a point. This genus includes five fpecies, of which three are found in our own country. Mr. Adams defcribes five other fpecies.

Species.

* Atomus. Whitifh, with a variable point. The animalculum itfelf appears as a white point, which, when highly magnified, is egg-fhaped: the fmaller end is generally marked with a black point, of which the fituation is fometimes varied, and found at the other end. Sometimes there are two black points feen croffing the middle of the body. Mr. Adams fays it was found in fea-water that had been kept the whole winter; it was not fetid, but no other fpecies of animalcula could be difcovered in the fame water.

Punctum. A folid opaque black point. The animalcula of this fpecies are very minute points, folid, opaque, and black, round and long. They are difperfed in the infufion, and move with a flow wavering motion, and were found in a fetid infufion of pears.

* Mica. This is tranfparent, or rather femi-tranfparent, like talc, with an oval moveable circle in the middle. It may be difcovered fometimes in very pure waters with the third lens of a fingle microfcope: when the magnifying power is increafed, it appears nearly fpherical, or oval, as it feems able to affume either of thefe forms at pleafure. There is a confiderable variety in its motions: it often turns round for a long time in the fame place. An appearance has been exhibited like two kidnies in the middle of the body, and the little animal is beautifully encompaffed with a kind of halo, arifing, moft probably, from invifible and vibrating fibrillæ.

* Lens. This, as its name imports, is tranfparent, with frequently

frequently a greenifh margin. It is nearly of a round figure, and fo pellucid, that it is not poffible to difcover the leaft veftige of inteftines. The animalcula of this fpecies are frequently feen collected together, forming a kind of vefi-cular or membranaceous mafs. The motions of the *lens* are in general rapid, and Mr. Adams fays that two united together may frequently be feen fwimming among the reft; while in this fituation they have been miftaken by obfervers for a different fpecies, but it is the fame generating another by divifion. It is found in almoft all kinds of water; alfo in infufions of animal and vegetable fubftances, myriads are faid to be contained in a fingle drop.

Termo. A moft minute fimple gelatinous point. Of this Mr. Adams obferves, "Among the various animalcula which are difcovered by the microfcope, this is the moft minute and the moft fimple; a fmall jelly-like point, eluding the powers of the compound microfcope, and being but imperfectly feen by the fingle; thefe and fome others of the Monas kind are fo delicate and flender, that it is no wonder they often efcape the fight of many who have examined infufions with attention; in a full light they totally difappear, their thin and tranfparent forms blending as it were with the water in which they fwim. Small drops of infufed water are often fo full of thefe, that it is not eafy to difcover the leaft empty fpace, fo that the water itfelf appears changed into another fubftance lefs tranfparent, but confifting of innumerable globular points, thickly fown together; which, though full of life, feem only a kind of inflated bladder. In this a motion may be perceived, fomething fimilar to that which is obferved when the fun's rays fhine on the water, the animalcula being violently agitated, or in commotion like a hive of bees."

Such are the fpecies defcribed in Gmelin's edition of Linnæus. Mr. Adams has mentioned five others as follow:

Ocellus. Trafparent like talc, with a point in the middle. The margin is black; it moves irregularly; is found in ditches covered with conferva, and frequently with the "Cyclidium milium."

Tranquilla. Egg-fhaped, tranfparent, with a black margin. The animalcula of this fpecies feem to be animated points, and nearly fixed to one fpot, where they have a fluctuating and reeling motion; they are frequently furrounded with a halo, like the *mica*, but differ in their figure, being fometimes fpherical, and fometimes quadrangular. They are found in urine kept fome time. This fluid is, after it has remained any length of time in the veffel, covered with a dark coloured pellicle, in which the little animals exift. In moft cafes a fingle drop of urine is fatal to animalcula, but the difcovery of thefe prove that there are beings of a peculiar kind appropriated to and flourifhing in it.

Lamellula. Flat and tranfparent. Found chiefly in fea-water. Its colour is whitifh, twice as long as it is broad, tranfparent, with a dark margin, the motion is vacillatory; it often appears as if it were double.

Pulvisculus. Tranfparent, with a green margin. The animalcula of this fpecies appear, when properly magnified, like fpherical pellucid grains of different fizes; the circumference is green, and a green bent line paffes through the middle of fome of them, fuppofed to indicate that they are feparating into two diftinct animalcula. They rove about with a wavering motion, and are found early in the fpring in marfhy grounds.

Uva. Tranfparent and gregarious. The animalcula of this fpecies, when collected in a heap, have a rotatory motion. The fmaller particles feparate from the larger, dividing, fometimes, into as many portions as there are conftituent particles in the group, when feparated they revolve with incredible fwiftnefs. "To try," fays Mr. Adams, "whether this group of animalcula was collected together by mere chance, or whether it was their natural ftate, the following experiment was made. A fingle corpufcle was taken the moment it was feparated from the reft, and placed in a glafs by itfelf; it foon increafed in fize, and when it had attained nearly the fame bulk as the group from which it was feparated, the furface began to affume a wrinkled appearance, which gradually changed till it became exactly fimilar to the parent group." The fame procefs was again tried, and with fimilar fuccefs. It is found in a variety of infufions.

MONASABA, in *Geography*, a town of Hindooftan, in Oude; 25 miles E. of Mahomdy.

MONASERAI, a town of Hindooftan, in the circar of Sumbulpour; 10 miles S.E. of Sumbulpour.

MONASIO, a town of Italy, in the department of the Lario; 15 miles N. of Como.

MONASTEER, a town of Africa, built by the Arabs, on a peninfula, which advances into the fea; 50 miles S.E. of Tunis.

MONASTER, a town of Ruffian Poland, in the palatinate of Kiev; 40 miles E. of Bialacerkiev.

MONASTEREVEN, a poft-town of Ireland, in the county of Kildare and province of Leinfter. It is fituated on the river Barrow, and the Athy branch of the grand canal paffes very near it. It has a flourifhing trade, and a confiderable population. There was an abbey here, which after the fuppreffion came into the Moore family. It ftill wears the venerable appearance, and retains the name of an abbey, and under the appellation of Moore abbey is the feat of the marquis of Drogheda. Monaftereven is 30 miles S.W. from Dublin, and 10 N.W. from Maryborough.

MONASTERII Provisor. See Provisor.

MONASTEROLO, in *Geography*, a town of France, in the department of the Stura; three miles N.W. of Savigliano.

MONASTERY, a convent, or houfe built for the reception of religious; whether it be abbey, priory, nunnery, or the like.

Monastery is only properly applied to the houfes of monks, mendicant friars, and nuns. The reft are more properly called *religious houfes*.

For the origin of monafteries, fee Monastic and Monk. The houfes belonging to the feveral religious orders, which obtained in England and Wales, were cathedrals, colleges, abbies, priories, preceptories, commanderies, hofpitals, friaries, hermitages, chantries, and free chapels. Thefe were under the direction and management of feveral officers. The diffolution of houfes of this kind began fo early as the year 1312, when the Templars were fuppreffed; and in 1323, their lands, churches, advowfons, and liberties, here in England, were given by 17 Edw. II. ftat. 3. to the priory and brethren of the hofpital of St. John of Jerufalem. In the years 1390, 1437, 1441, 1459, 1497, 1505, 1508, and 1515, feveral other houfes were diffolved, and their revenues fettled on different colleges in Oxford and Cambridge. Soon after the laft period, cardinal Wolfey, by licence of the king and pope, obtained a diffolution of above thirty religious houfes, for the founding and endowing his colleges at Oxford and Ipfwich. About the fame time a bull was granted by the fame pope to cardinal Wolfey to fupprefs monafteries, where there were not above fix monks, to the value

value of eight thousand ducats a year, for endowing Windsor, and King's college in Cambridge; and two other bulls were granted to cardinals Wolsey and Campeius, where there were less than twelve monks, and to annex them to the greater monasteries; and another bull to the same cardinals to enquire about abbies, to be suppressed, in order to be made cathedrals. Although nothing appears to have been done in consequence of these bulls, the motive which induced Wolsey, and many others, to suppress these houses, was the desire of promoting learning; and archbishop Cranmer engaged in it with a view of carrying on the Reformation. There were other causes that concurred to bring on their ruin: many of the religious were loose and vicious; the monks were generally thought to be, in their hearts, attached to the pope's supremacy; their revenues were not employed according to the intent of the donors; many cheats in images, feigned miracles, and counterfeit relics, had been discovered, which brought the monks into disgrace; the Observant friars had opposed the king's divorce from queen Catherine; and these circumstances operated, in concurrence with the king's want of a large supply, and the people's desire to save their money, to forward a motion in parliament, that, in order to support the king's state, and supply his wants, all the religious houses might be conferred upon the crown, which were not able to spend above 200*l.* a-year; and an act was passed for that purpose, 27 Hen. VIII. c. 28. By this act about 380 houses were dissolved, and a revenue of 30 or 32,000*l.* a-year came to the crown; besides about 100,000*l.* in plate and jewels. The suppression of these houses occasioned great discontent, and at length an open rebellion; when this was appeased, the king resolved to suppress the rest of the monasteries, and appointed a new visitation; which caused the greater abbies to be surrendered apace; and it was enacted by 31 Hen. VIII. c. 13. that all monasteries, &c. which have been surrendered since the fourth of February, in the twenty-seventh year of his majesty's reign, and which hereafter shall be surrendered, shall be vested in the king. The knights of St. John of Jerusalem were also suppressed by the 32 Hen. VIII. c. 24. The suppression of these greater houses by these two acts, produced a revenue to the king of above 100,000*l.* a-year, besides a large sum in plate and jewels. The last act of dissolution in this king's reign was the act of 37 Hen. VIII. c. 4. for dissolving colleges, free chapels, chantries, &c. which act was farther enforced by 1 Edw. VI. c. 14. By this act were suppressed 90 colleges, 110 hospitals, and 2374 chantries and free chapels. The number of houses and places suppressed from first to last, so far as any calculations appear to have been made, seems to be as follows:

Of lesser monasteries, of which we have the valuation	374
Of greater monasteries	186
Belonging to the hospitallers	48
Colleges	90
Hospitals	110
Chantries and free chapels	2374
Total	3182

Besides the friars' houses, and those suppressed by Wolsey, and many small houses, of which we have no particular account.

The sum total of the clear yearly revenue of the several houses at the time of their dissolution, of which we have any account, seems to be as follows:

	£	s.	d.
Of the greater monasteries	104,919	13	3½
Of all those of the lesser monasteries, of which we have the valuation	29,702	1	10½
Knights hospitallers head house in London	2,385	12	8
We have the valuation of only 28 of their houses in the country	3,026	9	5
Friars' houses, of which we have the valuation	751	2	0¼
Total	£ 140,784	19	3¼

If proper allowances are made for the lesser monasteries, and houses not included in this estimate, and for the plate, &c. which came into the hands of the king by the dissolution, and for the value of money at that time, which was at least six times as much as at present; and we also consider that the estimate of the lands was generally supposed to be much under the real worth, we must conclude their whole revenues to have been immense.

It doth not appear that any computation hath been made of the number of persons contained in the religious houses.

Those of the lesser monasteries dissolved by 27 Hen. VIII. were reckoned at about	10,000
If we suppose the colleges and hospitals to have contained a proportionable number, these will make about	5,347
If we reckon the number in the greater monasteries, according to the proportion of their revenues, they will be about 35,000; but as probably they had larger allowances in proportion to their number than those of the lesser monasteries, if we abate upon that account 5000, they will then be	30,000
One for each chantry and free chapel	2,374
Total	47,721

But as there were probably more than one person to officiate in several of the free chapels, and there were other houses which are not included within this calculation, perhaps they may be computed in one general estimate at about 50,000. As there were pensions paid to almost all those of the greater monasteries, the king did not immediately come into the full enjoyment of their whole revenues: however, by means of what he did receive, he founded six new bishoprics, *viz.* those of Westminster, (which was changed by queen Elizabeth into a deanery, with twelve prebends and a school,) Peterborough, Chester, Gloucester, Bristol, and Oxford. And in eight other sees he founded deaneries and chapters, by converting the priors and monks into deans and prebendaries, *viz.* Canterbury, Winchester, Durham, Worcester, Rochester, Norwich, Ely, and Carlisle. He founded also the colleges of Christ-church in Oxford, and Trinity in Cambridge, and finished King's college chapel there. He likewise founded professorships of divinity, law, physic, and of the Hebrew and Greek tongues, in both the said universities. He gave the house of Grey Friars, and St. Bartholomew's hospital, to the city of London; and a perpetual pension to the poor knights of Windsor; and laid out great sums in building and fortifying many ports in the channel. It is observable, upon the whole, that the dissolution of these houses was an act, not of the church, but of the state; in the period preceding the Reformation, by a king and parliament

ment of the Roman Catholic communion, in all points except the king's supremacy; to which the pope himself, by his bulls and licences, had led the way.

Although none, in this enlightened period, can approve either the original establishment or continued subsistence of monasteries; yet the destruction of them was felt and lamented, for a considerable time, as a great evil. One inconvenience that attended their dissolution was the loss of many valuable books, which their several libraries contained: for during the dark ages, religious houses were the repositories of literature and science. Besides, they were schools of education and learning; for every convent had one person or more appointed for this purpose; and all the neighbours that desired it might have their children taught grammar and church music there, without any expence. In the nunneries also young females were taught to work and read; and not only people of the lower rank, but most of the noblemen's and gentlemen's daughters were instructed in those places. All the monasteries were also in effect great hospitals, and were most of them obliged to relieve many poor people every day. They were likewise houses of entertainment for all travellers. And the nobility and gentry provided not only for their old servants in these houses, by corrodies, but for their younger children, and impoverished friends, by making them first monks and nuns, and in time priors and prioresses, abbots and abbesses. On the other hand, they were very injurious to the secular and parochial clergy, by taking on themselves many prebends and benefices, by getting many churches appropriated to them, and pensions out of many others; and by the exemptions they got from the episcopal jurisdiction, and from the payment of tithes. Nor were they less injurious to the nation in general, by depriving the public of so many hands, which might have been very serviceable to it in trade and other employments; by greatly diminishing the number of people, in consequence of the institution of celibacy; and by their houses or churches being sanctuaries for almost all sorts of offenders. And if the superstition had continued, and the zeal of establishing religious institutions had exerted itself with equal vigour to the present age, we should ere this have been a nation of monks and friars, or probably have become a prey to some foreign invader. We say nothing now of the acts of moral turpitude, which were committed in these abodes of celibacy and indolence; which, however they might have been exaggerated, were without doubt flagrant and atrocious. See Tanner's Notitia Monastica; and for an abstract, Burn's Eccl. Law, art. *Monasteries*.

MONASTIC, something belonging to monks, or the monkish life.

The monastic profession is a kind of civil death, which in all worldly matters has the same effect with the natural death.

The council of Trent, &c. fix sixteen years for the age at which a person may be admitted into the monastical state.

St. Anthony is the person who, in the fourth century, first instituted the monastic life; as St. Pachomius, in the same century, is said to have first set on foot the cœnobitic life, *i. e.* regular communities of religious.

In a short time the deserts of Egypt became inhabited with a set of solitaries, who took upon them the monastic profession. (See ANCHORET, HERMIT, &c.) St. Basil carried the monkish humour into the East, where he composed a rule, which afterwards obtained through a great part of the West.

In the eleventh century, the monastic discipline was grown very remiss. St. Odo first began to retrieve it in the monastery of Cluny: that monastery, by the conditions of its erection, was put under the immediate protection of the holy see, with a prohibition to all powers, both secular and ecclesiastical, to disturb the monks in the possession of their effects, or the election of their abbot. In virtue hereof, they pleaded an exemption from the jurisdiction of the bishop, and extended this privilege to all the houses dependent on Cluny. This made the first congregation of several houses under one chief immediately subject to the pope, so as to constitute one body, or, as they now call it, one *religious order*. Till then, each monastery was independent, and subject to the bishop. See MONK.

MONASTIER, in *Geography*, a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Le Puy; 9 miles S.S.E. of Le Puy. The place contains 1766, and the canton 8255 inhabitants, on a territory of 197½ kiliometres, in 9 communes.

MONASTIRSKA, a town of Russia, in the government of Tobolsk, on the Mura. N. lat. 57° 4'. E. long. 99° 24'.

MONATOO, a town of Bengal, in the province of Palamow, where is a passage across mountains to Koonda; 23 miles N.N.E. of Palamow.

MONAZZO, a town of Naples, in the province of Otranto; 14 miles S.E. of Tarento.

MONBACHIO, a town of Naples, in Principato Ultra; 15 miles E. of Conza.

MONBIN, or MOMBIN, in *Botany*, the French and Spanish name of a West Indian fruit, called by the English Hog Plum, *Spondias lutea*, Linn. Sp. Pl. 614; Monbin arbor foliis fraxini, fructu luteo racemoso; Plum. Nov. Gen. 44. t. 22. Madam Merian, who gives an excellent representation of this plant in her tab. 13, describes the fruit as of an astringent quality, but causing perspiration, which is of the same yellow colour as itself. See SPONDIAS.

MONBLANC, in *Geography*, a town of Spain, in Catalonia, on the river Francoli; 17 miles N. of Taragon.

MONBODDO, LORD, in *Biography*, so called according to the courtesy of the Scottish bar, and on this account he is more generally known by that title, than by his name of James Burnet, was born about the year 1714. He was educated at one of the Scotch universities, and paid a great attention to classical studies: but as soon as he had determined on the law as the future profession of his life, he passed through the ordinary course of juridical studies, and was, in the year 1737, admitted a member of the faculty of advocates at Edinburgh. His application to literary and juridical studies was almost incessant, and he acquired a high reputation for legal knowledge, as well as for an extensive acquaintance with the Grecian language and literature. In the year 1767 he obtained a judge's seat on the bench of the court of session, and performed with credit and honour the duties of that high office; insomuch that it is recorded, that no sentence passed by him was ever reversed by the house of peers. In the course of his literary studies, he was led to attempt the composition of a work, that might raise his name to distinction among men of letters, the main object of which is to prove the superior wisdom of the ancients, compared with that of the moderns. The first volume of his intended work, entitled "The Origin and Progress of Language," was given to the public in 1773, which was followed, at different periods, by five other volumes. With the philosophical history of language was involved necessarily that of civilization and knowledge; and what the author wrote on these subjects was perused by critics

critics with ſentiments of mingled reſpect, deriſion, and indignation. His lordſhip had, however, many advocates, whoſe zeal, to ſay the leaſt, was in every reſpect equal to their knowledge and learning. Thoſe who were partial to modern literature, ſays a biographer of lord Monboddo, on account of their ignorance of, and inability to enter into that of antiquity; or who, though not unacquainted with the more popular of the ancient authors, were, however, ſtrangers to the deeper myſteries of Greek erudition, condemned lord Monboddo's work with bitter and contemptuous cenſure. The Scotch literati generally held the labours of their countryman in much diſeſteem; but in England its reception was more favourable to the author's expectations. Here were found ſome critics of univerſally acknowledged talents and profound learning, who, while they ſmiled at many of his ſtrange notions and hypotheſes, were willing to applaud him for the ſervice he had done to the intereſts of learning. In the late Mr. Harris, the author of Philoſophical Grammar, and other erudite works, he found an admirer and literary friend, who was exceedingly delighted to meet with a perſon that had cultivated thoſe ſtudies with an ardour equal to what he had himſelf beſtowed on them, and who almoſt worſhipped the excellence of the ancient Greeks, as far ſurpaſſing all other excellence. While lord Monboddo was proceeding in his publication of this work, he commenced the compoſition of a larger undertaking, with the expreſs view of unfolding and vindicating the principles of Grecian philoſophy. This work, entitled "Ancient Metaphyſics," conſiſted of five volumes, quarto, of which the firſt was publiſhed in 1779, and the laſt appeared after the author's death. In this he vainly attempts to revive the abſurd principles of the Ariſtotelian philoſophy, and treats modern ſyſtems, not excepting that of the immortal Newton, with a ſort of ridicule and contempt, that only expoſed himſelf to well merited deriſion, or to the more worthy emotions of pity and compaſſion. Lord Monboddo's private life was ſpent in the practice of all the ſocial virtues, and in the enjoyment of much domeſtic happineſs. He married an amiable lady, by whom he had a ſon and two daughters; but of theſe joys in the cup of life, he was quickly bereaved by the loſs of his ſon and wife,—afflictions which cut deep to the heart: but like a true philoſopher, when he found ſorrow of no avail, he rouſed himſelf to exertion, and called forth his Chriſtian principles, which, in the midſt of calamity, led him to truſt and hope in him who gave, and who has a right to take away.

He was now offered, in addition to his place as judge in the ſupreme civil court in Scotland, a ſeat in the court of juſticiary, the ſupreme criminal court, on which he would have done the higheſt honour, compared with ſome of the men who have ſince ſat there, and who will be everlaſtingly remembered for their ſentences in the years 1793, 1794, &c. Though the ſalary of this office would have produced a convenient increaſe of his income, he was ſatisfied with his preſent emoluments, and refuſed to accept what had been offered, leſt its buſineſs ſhould too much detach him from his favourite ſtudies. His patrimonial eſtate did not amount to more than a clear income of 300*l. per annum*, yet he would never raiſe his rents, ſuppoſing that he was by this means ſerving his tenants; an idea unqueſtionably founded in error. We have known many inſtances, in which land has been vaſtly improved, and tenants enriched, by demanding of them a riſe in their rents, correſponding to the increaſed demands of the times. The error of lord Monboddo was, however, very venial: it originated from the beſt and moſt humane motives. He ſhewed, indeed, at no time a particular ſolicitude for any great improvement of his lands: his main object was, that the perſons who lived on them ſhould be amply ſupported by the produce. The vacations of the court of ſeſſion afforded him leiſure to retire every year, in the ſpring and autumn, to the country, where he was accuſtomed to dreſs in a ſtyle of ſimplicity, as if he had been only a plain farmer, and to live among the people upon his eſtate with all the kind familiarity and attention of a father among his children. In this ſtate he had a viſit from Dr. Samuel Johnſon; and though, probably, no two perſons could differ more than theſe, yet lord Monboddo was too hoſpitable to enter into any contentious diſcuſſions with a ſtranger in his own houſe. His lordſhip frequently viſited London, during his vacations; to which city he was allured by the great number of men of profound erudition, whoſe converſation he had an opportunity of enjoying there. In all his journies he was accuſtomed to ride on horſeback, attended by a ſingle ſervant. On his return from the laſt viſit, which he made purpoſely to take leave of his friends, he was taken ill on the road, and would probably never have reached home, had not a friend overtaken him, and prevailed on him to travel the remainder of the way in his carriage. His lordſhip died in June 1799, in the 85th year of his age. Although rigidly temperate in his habits, he delighted much in the convivial ſociety of his friends; and among theſe he could number all the moſt eminent characters in Scotland for virtue, literature, and real elegance of converſation. Of his various excellencies we have heard much from a noble lady, now herſelf no more, who never ceaſed to cheriſh his memory with reſpect and honour.

MONBRUN, in *Geography*, a town of Africa, in the kingdom of Hoval; 15 miles S.W. of Gourbel.

MONBUEY, a town of Spain, in the province of Leon; 30 miles S.S.W. of Aſtorga.

MONCADA, a town of Spain, in Catalonia; 8 miles N. of Barcelona.—Alſo, a town of Spain, in Valencia; 7 miles N.W. of Valencia. This town is now reduced to a village: it has a pariſh church, a convent of Dominicans, and a population of about 1000 inhabitants.

MONCALIER, a town of France, in the department of the Po, on an eminence near the river, containing two churches, ſeveral convents, and a royal palace; 4 miles S. of Turin.

MONCALVO, a town of Iſtria; 7 miles S. of Rovigno.—Alſo, a town of France, in the department of Marengo; 9 miles N. of Aſti.

MONÇAON, a ſmall but fortified town of Portugal, in the province of Entre Duero é Minho, on the Minho; 25 miles N. of Braga. N. lat. 42°. E. long. 8° 10.

MONÇARAS, a town of Portugal, in Alentejo, on the Guadiana, containing more than 1500 inhabitants; 25 miles E. of Evora.

MONCAYO, a town of Spain, in Aragon; 11 miles W. of Borja.

MONCHABOO, a town of the Birman empire, which was formerly its capital; 52 miles N. of Ava. N. lat. 22° 34′. E. long. 97° 40′.

MONCLAR, a town of France, in the department of the Lot, and chief place of a canton, in the diſtrict of Montauban; 10 miles E.S.E. of it. The place contains 1776, and the canton 5267 inhabitants, on a territory of 150 kiliometres, in 8 communes. N. lat. 43° 58′. E. long. 1° 40′.—Alſo, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the diſtrict of Villeneuve-d'Agen; 7 miles weſt from it. The place contains

contains 2061, and the canton 8462 inhabitants, on a territory of 150 kiliometres, in 10 communes.

MONÇON, a town, with a castle, of Spain, in Aragon, on the river Cinca; 25 miles N.W. of Lerida.

MONCONTOUR, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Loudun; 7 miles S.S.W. of Loudun. The place contains 819, and the canton 7173 inhabitants, on a territory of 212½ kiliometres, in 18 communes. N. lat. 46° 53′. E. long. 0° 4′.—Also, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of St. Brieuc; 10 miles S.S.E. of St. Brieuc. The place contains 1685, and the canton 14,380 inhabitants, on a territory of 215 kiliometres, in 11 communes.

MONCONYS, Balthasar de, in *Biography*, a writer of travels, was born at Lyons, and received the early part of his education in the Jesuits' college of that city. The plague, which in 1628 desolated many countries, at this period, forced him to quit his native place; and he went to Spain, where he completed his studies at the university of Salamanca. He attached himself to mathematics, chemistry, and astrology; and in Portugal, which he visited, he gained considerable reputation by his facility in forming horoscopes. From Portugal he travelled into the East, for the purpose of increasing his knowledge in the occult sciences, as they were falsely called, and tracing the remains of the philosophy of Hermes Trismegistus, and Zoroaster. Discovering, perhaps, the vanity of the pursuit, he returned to France, and devoted himself to mathematical and physical studies, which engaged him in correspondence with most of the learned men of his time. He died at Lyons in 1665; soon after which his travels were published, in three volumes, quarto: they are said to contain many rare and very curious observations. Moreri.

MONCOORAH, in *Geography*, an island in the mouth of the Ganges, about twelve miles long, and three broad. N. lat. 22° 10′. E. long. 91° 10′.

MONCOQ, a town of France, in the department of the Lot, and chief place of a canton, in the district of Cahors; 12 miles S.W. of Cahors. The place contains 1970, and the canton 10,804 inhabitants, on a territory of 205 kiliometres, in 16 communes. N. lat. 44° 20′. E. long. 1° 17′.

MONCRIF, Francis-Augustin Paradis de, in *Biography*, a French poet and polite writer, was born of a family in middle life, at Paris, in 1687. Though intended for a business suited to his rank in society, he devoted himself to literature, hoping to obtain the patronage of some person of consequence. One of his earliest compositions was an "Ode on the Death of Louis-le-Grand," by which he expected to conciliate the favour of the regent. But he did not excel in lyrics, and is chiefly distinguished by small theatrical pieces, complimentary verses, madrigals, and ballads, which the French call *romances*. He was an actor as well as a writer, read with grace, and acted in a very agreeable way in the dramatic interludes then in vogue, and thus rendered himself acceptable to the most cultivated societies; at the same time, by his discretion and good humour, avoided every thing that might give offence. He obtained the posts of private secretary to the count of Clermont, and reader to the queen, and was admitted to many honours in the court of Lewis XV. He did not live wholly to himself, but was liberal to his poor relations, zealous in the service of his friends, and grateful for past favours; an instance of which last quality he gave, in his request to be allowed to follow into his retreat the count d'Argenson, who was exiled in 1757. Moncrif lived enjoying perfect health till a very short time before his death, which took place in 1770, when he had attained the age of 83. As an author, his principal productions are "Essai sur la Necessité et sur les Moyens de plaire," which is a very instructive work on the art of becoming agreeable in society; "Les Abderites," a comedy; "Poesies diverses;" some dissertations; and several little dramatic pieces of the opera kind. His "Histoire des Chats" was a trifle of the sportive kind. His works have been published collectively in four volumes.

MONDA, or Munda, in *Geography*, a town of Spain, in Grenada, near which Cæsar gained a victory over the sons of Pompey; 23 miles W. of Malaga.

MONDAGELE, a town on the east coast of Ceylon; 28 miles S. of Trincoli.

MONDAHU, a river of Brazil, which runs into the Atlantic, S. lat. 3° 10′. W. long. 40° 46′.

MONDARA, a town of Nubia; 40 miles S.W. of Dekin.

MONDAY, Plough. See Plough.

Monday *Bay*, in *Geography*, a bay on the coast of Terra del Fuego, in the straits of Magellan, affording good anchorage in 20 fathoms; 15 miles S.E. of Cape Upright.

MONDEGO, a river of Portugal, which rises near Guarda, in the province of Beira, and discharges itself into the Atlantic, 12 miles S.W. of Montemor e Velho.

MONDEJAR, a town of Spain, in New Castile; 25 miles E. of Madrid.

MONDELLO, a town of Sicily, in the valley of Mazara; 8 miles N. of Palermo.

MONDIM, a town of Portugal, in the province of Beira; 10 miles S.S.E. of Lamego.

MONDINO, or in Latin Mundinus, in *Biography*, a physician deservedly celebrated in the dark ages, was born at Milan, according to Freind, and flourished early in the 14th century. He held the professorship of medicine at Bologna in the year 1316, and enjoyed an extensive reputation throughout Italy, then the great seat of science, for his medical skill. His principal claim to distinction, however, rests upon his zeal and success in the cultivation of anatomy, of which art he must be deemed the restorer, having been the first among the moderns who dissected human bodies. He was the author of a work, entitled "Anatomia omnium humani Corporis interiorum Membrorum," first printed at Pavia in 1478, and afterwards frequently republished, with various commentaries. It is a methodical treatise, very copious upon the subject of the viscera, in the description of which he introduced many original observations, but passes lightly over the subject of the nerves and blood-vessels. It abounds, however, with a multitude of errors, resulting from his attachment to the opinions of Galen and Avicenna, and is marked by the rudeness and inaccuracy of the times. Nevertheless, it conferred a real benefit on the infant science, and acquired such a high character for authority in Italy, that the statutes of Padua, and some other medical schools of Italy, prohibited the use of every other work, as a text-book for the students of anatomy: and it continued in this general estimation for nearly two centuries. Mundinus died at Bologna in 1325, or 1326, and was buried in the church of St. Vital. Freind's Hist. of Med. Eloy Dict. Hist.

MONDONEDO, in *Geography*, a town of Spain, in Galicia, 25 leagues N.E. of St. Jago, and at a similar distance W. of Oviedo, is surrounded by mountains; situated at the bottom of a hill, at the entrance of a fertile and pleasant valley, and in the midst of several springs and brooks, and separated by the

the two rivers Sigto and Ruzos from its suburbs. It is the see of a bishop, suffragan of Compostella, and has seven churches, including the cathedral and convents, one chapter of canons, one seminary, one oratory, and two hospitals. The town, which is tolerably large, is encompassed by walls, and has five gates and two bridges. The houses are tolerably built, of good stone; the streets are rather narrow, but regular; the grand square is watered by a fountain, and many other fountains cool and cleanse the streets. The air is very salubrious. The population consists of 5600 persons. The place is defended by the castle of Castro Oro. The river Mino rises at a little distance north of this town.

MONDONEDO, *Sierra de*, a mountain of Galicia of great extent, occupying the whole extremity of the north-east of Galicia, towards the Asturian boundary to the east, and proceeding to the north as far as Cabo Ortegal, and to the west as far as the Atlantic ocean.

MONDONVILLE, JOHN JOSEPH CASSANEA DE, in *Biography*, born at Narbonne in 1711, owes his reputation and his fortune to incessant diligence and toil, a great passion for his art, and a regular conduct. He at first acquired his reputation by the violin: he was the rival of the famous Guignon, who was at the head of his art. They executed together at the Concert Spirituel, and varied with great taste numerous favourite airs in duo, to the infinite satisfaction of the public. He is celebrated by the famous Le Cat of Roan, for producing the *sons harmoniques* upon his violin, of which art he seems to have been the first who distinguished himself.

He composed sonatas for the harpsichord, with an accompaniment *obligato* for the violin, which at one time were in high favour all over Europe. After this, motets for a single voice, accompanied by difficult lessons on the harpsichord, which gained him the place of master of the chapel royal. He directed the Concert Spirituel during many years with great reputation, and likewise composed several pieces for the opera, which had great success.

M. Laborde, from whom this article is extracted, has recorded his private character in a way that does his memory more honour, perhaps, than his compositions; which, though in great favour in these days at Paris, were always too much cast in a French mould to be equally admired elsewhere. His melody was national, but his accompaniments were spirited and ingenious. He died in 1772, at 61.

MONDOVI, in *Geography*, a town of France, in the department of the Stura, late capital of a small province in Piedmont, to which it gave name; situated at the foot of the Apennines, on a mountain near the river Ebro. It was erected into a bishopric by pope Urban VI. in 1388, under the archbishopric of Turin. Besides the cathedral, it has five parish churches, an university, twelve convents, and about 10,000 inhabitants. It was taken by the French, after a splendid victory, in 1796; 30 miles S. of Turin. N. lat. 44° 24'. E. long. 7° 56'.

MONDRAGON, a town of Spain, in the district of Guipuscoa, in the province of Biscay, near which are medicinal springs, and a mine of excellent iron; 24 miles S.S.W. of St. Sebastian.

MONDRAGONE, a town of Naples, in Lavora, near the sea-coast, celebrated on account of its medicinal baths; 13 miles N.W. of Capua.

MONDUKOLSKOI, a town of Russia, in the government of Irkutsk, on the borders of China. N. lat. 50° 8'. E. long. 103° 24'.

MONEAH, a town of Hindoostan, in Bahar, on the right bank of the Ganges; 17 miles W. of Patna.

MONEBA, a town of Africa, in Calbari, on the Camaroners. N. lat. 3° 40'.

MONEDA, a town of Sweden, in the province of Smaland; 14 miles N.W. of Wexio.

MONEDULA, JACKDAW, in *Ornithology*, a species of *Corvus*; which see.—Also, a species of Crotophaga. See CROTOPHAGA *Ani*.

MONEER, in *Geography*, a town of Hindoostan, in Bahar; 23 miles N.W. of Saseram.

MONEGAL, a town of Hindoostan, in Golconda; 33 miles S. of Combamet.

MONEGLIA, a town of the Ligurian republic; seven miles W. of Brugneto.

MONEINS, a town of France, in the department of the Lower Pyrenees, and chief place of a canton, in the district of Oleron; 9 miles W. of Pau. The place contains 5550, and the canton 11,004 inhabitants, on a territory of 157½ kilometres, in 7 communes.

MONEMERION, Μονημεριον, among the ancient Romans, a show, according to some, wherein none but tame beasts were exposed to view.

Others will have it to be a show of one day's continuance.

MONESTIER, in *Geography*, a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Briançon; 13 miles N.W. of Gap. The place contains 2708, and the canton 4736 inhabitants, on a territory of 212½ kiliometres, in three communes.

MONESTIER-*de-Clermont*, a town of France, in the department of the Isere, and chief place of a canton, in the district of Grenoble; 16 miles S. of Grenoble. The place contains 569, and the canton 4258 inhabitants, on a territory of 355 kiliometres, in 10 communes.

MONESTIES, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Alby; 9 miles N. of Alby. The place contains 1210, and the canton 8101 inhabitants, on a territory of 250 kiliometres, in 18 communes.

MONETA, or JUNO MONETA, in *Mythology*, the goddess of money, who had a temple at Rome, is represented upon medals with the instruments of coinage, the hammer, the anvil, the pincers and the die, with the Latin word "moneta." Others say, that this name is formed from *moneo*, I warn or advise, because a little before the Gauls besieged Rome, she had warned the people to buy a sow big with young, an etymology that is supported by the authority of Cicero: "Junonem appellatam monetam, a moneo videlicet verbo, denominatam." See MONEY.

MONETÆ PES. See PES.

MONETAGIUM, MONETAGE, or *Mintage*, the right or privilege of coining money.

MONETALES TRIUMVIRI. See TRIUMVIRI.

MONETARIUS, or MONEYER, a name which antiquaries and medallists give to those who struck the ancient coins or monies.

Many of the old Roman, &c. coins have the name of the monetarius, either written at length, or at least the initial letters of it. See MEDAL.

MONETIA, in *Botany*, received its name from L'Heritier, in compliment to the celebrated J. B. de Monet, Chevalier de Lamarck; see LAMARCKIA.—L'Herit. Stirp. Nov. 1. t. 1. Schreb. 81. App. 813. Willd. Sp. Pl. v. 1. 669. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 264. (Azima; Lamarck Dict. v. 1. 343. Illustr. t. 807. Juss. 425.)—Class and order, *Tetrandria Monogynia*, L'Herit. (*Dioecia Tetrandria*, Schreb. 813.) Nat. Ord. uncertain.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, fwelling, permanent, cloven into four, lanceolate, acute, reflexed fegments, two of which are deeper than the reft. *Cor.* Petals four, linear, acute, recurved, longer than the calyx. *Stam.* Filaments four, erect, inferted into the receptacle, almoft as long as the corolla; anthers ovate, incumbent. *Pift.* Germen fuperior, nearly fquare, terminating in a thickifh, conical ftyle, fhorter than the ftamens; ftigma acute. *Peric.* Berry? juicelefs, globular, with a little point, furrounded by the calyx, of two cells? *Seeds* folitary, flat on one fide, convex on the other.

Obf. The flowers are occafionally trifid or bifid.

Eff. Ch. Calyx inferior, four-cleft. Corolla of four petals. Berry? of two cells. Seeds folitary.

1. M. *barlerioides*. Four-fpined Monetia. L'Herit. Stirp. Nov. t. 1. Willd. Thunb. Prodr. 28. (Azima tetracantha; Lamarck Dict. v. 1. 343. Lycium indicum fpinis quaternis ad foliorum fingulorum exortum; Seb. Thef. v. 1. 21. t. 13. f. 1.)—Spines four. Leaves fmooth on both fides. Native of India, and the Cape of Good Hope. It flowers in the ftove about Auguft or September. This is a middling-fized fpinous fhrub, refembling *Barleria hyftrix* in habit. *Root* perennial, woody, branched, cracked, with the tafte of liquorice. *Stem* erect, full of chinks, afh-coloured. *Branches* oppofite, diffufe, denfe; the fmaller ones prickly, deflexed, fquare, green at firft, afterwards greyifh. *Shoots* green, naturally downy, but becoming fmooth by culture. *Prickles* four together, croffing each other horizontally, awl-fhaped, fharp-pointed, withering at the tip, with one internal ftreak, about half as long as the leaves. *Leaves* oppofite, on very fhort ftalks, fpreading, ovate, pointed, entire, ribbed. *Flowers* axillary, on the young fhoots, about three in a clufter, fometimes folitary, feffile and herbaceous. *Bracteas* two-leaved, oppofite, adhering to the flowers laterally, very narrow, acute, changing into prickles.

2. M. *diacantha*. Two-fpined Monetia. Willd. (Azima diacantha; Lamarck Dict. v. 1. 343. Amaranthoides indicum verticillatum parietariæ hirfutis foliis, fpinofum; Pluk. Alm. t. 133. f. 3. Tsjérou-Kára; Rheed. Hort. Malab. v. 5. 73 t. 37.)—Spines two. Leaves downy beneath. Native of India.—This is an evergreen fhrub, rifing to the height of fix feet, with a thickifh *ftem*, and numerous afh-coloured *branches*, which are very fpinous. *Leaves* two or three together, almoft feffile, roundifh-oblong, thick, clofe; dark green, fmooth and fhining above, paler and hairy beneath. *Flowers* axillary, at the bafe of the fpines, fmall and greenifh. The whole herb has a bitter flavour.

Mr. Dryander, in his remarks on Profeffor Gmelin's edition of the *Syftema Naturæ*, Linn. Tranf. v. 2. 221, obferves "that *Azima nova* he fuppofes is meant for *Azima tetracantha* of Lamarck. *A. diacantha* being only taken from Plukenet's figure, is confequently doubtful."—We have however retained it after the example of Willdenow, relying upon the accuracy of Rheede's defcription and figure.—Kanden-Kára; Rheed. Hort. Malab. v. 5. 71. t. 36, feems undoubtedly of this genus, and perhaps merely a variety of *diacantha*.

Schreber, on revifing this genus, has removed it from *Tetrandria* to *Dioecia*, a meafure, of which we do not fee the propriety, both organs being prefent in all the flowers, though, as it appears, each is occafionally defective.

MONETOU Islands, in *Geography*, two iflands in lake Michigan. N. lat. 44° 50′. W. long. 85° 28′.

MONEY, in *Commerce*, is a general term for coin, paper, or any other meafure of value, or reprefentative of property, that paffes current from hand to hand as a circulating medium. See Bank, Cash, Circulation, Coin, Currency, Exchange, Paper *Money*, and Political *Economy*. For an accurate definition of money, fee the next article.

The origin of money feems to have been coeval with the firft regulations of civil fociety, or at leaft it is too remote to be traced by any authentic hiftory. The invention of this common meafure, or ftandard, according to which all other things fhould be eftimated, is afcribed by fome perfons, on the authority of Jofephus, to Cain; although the firft information that has been tranfmitted concerning it, originates with the patriarch Abraham, who paid 400 fhekels for a burying place. The Greeks refer the invention of money to Hermodice, wife of king Midas; and the Latins to Janus. Barter, that is the exchange of one commodity for another, was the ordinary mode of traffic in the earlier periods of the world: thus we find in Homer, that Glaucus's golden armour was valued at 100 oxen, and Diomedes's armour at 10. This method, which ftill obtains among favage nations, muft have been found extremely inconvenient in the early ages of commerce, and hence the neceffity of adopting fome commodity of general utility and demand as a meafure of value. This neceffity and its expedient are well explained by Ariftotle in his Politics (book i. chap. 6.) "All ufeful things," fays the philofopher, "could not, without great difficulty, be tranfported from place to place, it was refolved, by common confent, that in bartering commodities, they fhould reciprocally give and receive fome fubftance, which, being in its nature applicable to the purpofes of life, might, at the fame time, be eafily carried about."

The fubftance which has been adopted as a circulating medium, or meafure of value, has been various in different ages and countries. In Italy it was originally cattle, if we may judge from the Latin word *pecunia*, money, which is faid to be derived from *pecus*, a herd or flock. Thus Scaliger fays, "à pecu formatur pecunius, undè pecunia: fubintelligatur res vel quid fimile, et ficut veterum divitiæ confiftebant in copia pecudis, ita moneta pecudis effigie primùm notata fuit. Et apud Athenienfes nummi figurâ boum fignati fuerunt." Pliny fays, that money was called *pecunia*, becaufe their firft coin was ftamped with the figure of a cow. The Latin word *moneta* for money is however probably more modern than *pecunia*, and is faid to be derived from *moneo*, to advife or mark, that is, to fhew by fome mark the weight and finenefs of the metal of which coins were compofed. Thus, according to Ifidorus, "Moneta ita appellatur, quia monet nè qua fraus in pondere vel metallo fiat." In favour of this etymology, Suidas obferves, that when the Romans were in want of money, Juno *admonifhed* them to practife juftice, and then there would be no want of money; and when they had found the good effect of this counfel, fhe was furnamed *Juno Moneta*, and money was coined in her temple. In procefs of time, money was made a goddefs, and enfhrined by the name of *Dea Pecunia*, under the figure of a woman holding a balance in one hand, and a cornucopia in the other.

In all nations where commerce has made any confiderable progrefs, the precious metals, either in coins or ingots, or their reprefentative value in paper, have been adopted as money. Other fubftances, however, are ftill ufed for this purpofe in different countries, efpecially for the common or inferior purpofes of trade, as cowries or fmall fhells in India, and falt bricks, and beads, in Abyffinia. See Coin, and the fequel of this article.

As we have already given an account of the progrefs and prefent ftate of metallic monies under the article Coin, and of monies of exchange under the head Exchange, it remains here to explain what is to be underftood by monies of account, and to ſtate their names in different countries, and alſo their value compared with ſterling.

Money is diſtinguiſhed into real and imaginary. By real money is underſtood coin, or any other circulating medium, and by imaginary, or ideal money, a nominal ſum, which is not repreſented by any piece or coin, but which is uſed in keeping accounts, as the pound ſterling, the livre Tournois, &c.

Imaginary monies have had their origin, for the moſt part, in real coins, or in weights. Theſe units, which were originally adopted as meaſures of value, have been always continued under the ſame denomination, notwithſtanding the fluctuations which may have taken place in the prices of metals, or of merchandize. There are, however, imaginary monies which have not thus originated, but have been contrived for the purpoſe of ſimplifying accounts, as the centimes of France, and the cents in America. It ſhould, however, be obſerved, that all monies of account are not imaginary, nor are they, in all places, the monies of exchange, but they are moſt generally ſo.

In order to underſtand the monies of account in the following table, ſome preliminary explanations may be neceſſary.

Monies are diſtinguiſhed in different countries by particular denominations, as *ſpecie*, *effective*, *currency*, *banco*, *giro*, *moneta di cambio*, *caſh*, *valuta*, *&c.*

Specie and *effective* generally mean coin, but in Germany the word *ſpecie* is applied to the rix-dollar and its diviſions, as coined after the rate of the empire.

Currency moſtly ſignifies the common or current money of a place, which, in Holland, is called *caſſe*, in Venice *moneta piccola*, and in other parts of Italy *moneta lunga*; but in ſome parts of Germany, and particularly in Augſburg, currency means money of account, and it has the ſame meaning in America and the Weſt Indies, where it derives its name from a paper currency which has been long depreciated and diſcontinued.

Banco is the money which is placed in banks of depoſit, and which is not drawn out, but transferred from one perſon to another, in the payment of debts and contracts.

Giro, in moſt parts of Germany, means money of exchange, which in Italy is called *moneta di cambio*.

Caſh generally means real money, but in Hanover the term is applied to a certain ſuperior kind of money uſed for large payments, as diſtinguiſhed from another ſort, uſed in inferior departments of buſineſs, called old value. The word caſh is likewiſe applied to a ſmall coin in China, and in ſome parts of India beyond the Ganges.

The word *valuta*, or *valeur*, is applied in moſt parts of the continent of Europe to the prices or rates at which different kinds of monies are reckoned in commercial tranſactions.

The difference of one ſort of money compared with another is moſtly reckoned at ſo much *per cent.* When a better ſort is given for a worſe, the premium or per centage is called *agio*. But when the difference or per centage is conſidered with regard to the inferior ſort of money, it is called *diſcount*. *Diſcount* is likewiſe a term applied to an allowance of ſo much *per cent. per annum* for the payment of money before it becomes due, and this diſcount differs from the former as *agio* differs from *intereſt*.

Intereſt is an allowance of ſo much *per cent. per annum* for the uſe of money, and is therefore an addition to the principal, but *agio* adds nothing to the capital, being only the actual difference in value. In the ſame manner diſcount between different ſorts of monies, and diſcount for prompt payment differ; in the former caſe there is no loſs nor diminution, but in the latter there is a deduction from the principal. See Agio, Interest, and Discount.

The following table, which we extract, by permiſſion, from the Univerſal Cambiſt, will ſhew the value of the principal monies of account of the chief trading places, in ſterling, according to the mint regulations of thoſe countries compared with the mint laws of England; and though moſt of the monies are imaginary, yet, as they repreſent certain ſums of coined money, their value is thence eaſily known.

Table of Monies of Account, containing the Value of the Monies of Account of different Places (expreſſed in Pence and Decimals of Pence), according to the Mint Price both of Gold and Silver in England; that is, *3l. 17s. 10½d. per* Oz. for Gold, and *5s. 2d.* per Oz. for Silver.

We fhall here fubjoin fome additions to the hiftorical part of the prefent article, as well as to that of COIN and COINAGE, to which the reader is referred.

Among the ancient Britons, iron rings, or, as fome fay, iron plates, or tin plates and rings, were ufed for money. Among the Lacedæmonians, iron bars were quenched with vinegar, thus intending that they fhould not ferve for any other ufe. Seneca obferves, that there was anciently ftamped money of leather, *corium forma publica impreffum*; and the fame thing was put in practice by Frederic II. at the fiege of Milan; to fay nothing of an old tradition among

among ourselves, that, in the confused time of the barons wars, the like was done in England. In 1360, king John of France, who agreed to pay our Edward III. for the ransom of his person 3,000,000 of gold crowns, was reduced to the necessity of paying for the necessaries of his houshold in leather money, in the middle of which there was a little nail of silver. The Hollanders, we know, coined great quantities of pasteboard in the year 1574. Numa Pompilius made money of wood and leather; nor does it appear that the Romans were much acquainted with the art of striking money in metal during the time of their kings. There is reason to believe, that both gold and silver money were very early in use in Egypt and Asia, and thence soon afterwards introduced into Carthage and Greece. From Greece it was brought to Rome, and thence gradually westward into all the Roman provinces.

The first shape, says Mr. Pinkerton, in which money appeared, was that of pieces of metal without any stated form or impression, but merely regulated to a certain weight; for *weight* was the grand standard of ancient coinage, so that all large sums were paid in weight even down to the Saxon period of England. With us weight is now applied to each particular piece, and that only in gold: whereas, with the ancients, weight was applied to the sum total; to silver as well as gold; nay, in some instances, to brass. In Greece large sums were referred to so many "Mnæ," or "Minæ," and also to the larger denomination of so many "Talents." (See MINA and TALENT.) As in Greece the first estimation of money was merely by weight, this was likewise the case in Rome. Silver was the metal first used in Grecian coinage, but copper in the Roman; the former metal having been long unknown to the Romans. The first valuation of Roman money was by the "libra gravis æris," or pound of heavy brass; and when by the progress of their conquests they obtained silver and gold, these were regulated in the same manner. The common Roman pound, yet used at Rome, consisted of 12 ounces of 458 grains each, equal to our ounce avoirdupois; but the money ounce seems to have had only 420 troy grains, and the pound 5040. This was the standard of copper; and when silver came to be coined, seven denarii went to the ounce, as in Greece eight drachms: the gold was regulated by the scriptulum, scrupulum, scruple, or third part of a denarius, and by the larger weights just mentioned. (See DENARIUS, ÆS, and SESTERTIUS.) Money in old Rome, when rising to a high sum, was estimated not by the talent, a term unknown to the Romans, but by the hundred weight of brass, called "Pondus" by way of eminence. See SESTERTIUM.

As to the origin of the Roman coinage we may observe, that the states adjoining to Latium, and from which most probably the form of the first Roman coinage was derived, were, on the N. and W. the Etruscans; and upon the S. and E., at a great distance, the Grecian colonies in Magna Græcia and Sicily. To the Etruscans Mr. Pinkerton ascribes the origin of the Roman coinage, and not to the Grecian colonies, or to the Sicilians. (See LIBRA.) The first Roman coinage, according to Pliny and other respectable authors, took place in the reign of Servius Tullus in the year 460 B.C., or according to the common calculation 550 years B.C. The coinage of Tullus seems to have been confined to the As, Æs, or piece of brass only. (See AS.) The largest imperial brass coin was a piece of the value of two-pence English, called "Sestertius," which see. Before the time of the first Cæsar, as Mr. Pinkerton thinks, yellow brass began to be used in the Roman coinage, and this was always considered as double in value to the Cyprian, or copper. From Augustus downward, the large brass were all of the yellow sort, and not one of them copper. The largest of those that are called the middle size were likewise all of yellow brass; and that of the next size, which is the As, weighing the half ounce, is universally copper. The orichalcum, or what we term brass, was by the ancients held in far superior esteem to copper, or the "Æs Cyprium." It is observed, that all the large brass coins were of yellow metal, and the middle brass yellow, or red; but the former were always of the finest workmanship. The rust, with which time covers them, has confounded them together, and our putting little more value on brass than on copper hath confirmed the deceit, whereas the ancients put double the value on brass that they put on copper; but the large brass should not be taken for copper, because they sometimes have now a copper hue: before the person who examines can decide, he must always scrape the side of the metal; and he will thus learn that the ancient coinages of brass and of copper were kept as distinct as those of gold and silver. (See SESTERTIUS.) Under Valerian and Gallienus, there appeared a new coinage of copper washed with silver. Coins of this sort are just the size of the denarius; and, indeed, they are the "denarii," or "philippei ærei." See DENARIUS and FOLLIS. For an account of the silver coinage of Rome; see DENARIUS.

The gold coinage of Rome took place, according to Pliny, sixty-two years after silver, that is, in the 547th year of the city, by vulgar account, or 204 B.C. At that time the scruple, which even now remains, passed for 20 sesterces. Afterwards it was thought proper to coin 40 pieces out of the pound of gold; and by degrees this weight was diminished to 45 in the pound. See SCRUPLE.

The aureus, or common gold coin, in the first coinage was worth 30 silver denarii, equal to 1*l.* sterling; gold being to silver as $17\frac{1}{7}$ to 1. It thus continued till Sylla's time, when it weighed no less than 166 grains at an average, or 30 in the pound of gold. About the year of Rome 675, 77 years B.C., the aureus fell to the rate of 40 to the pound, and passed for 20 denarii. In the reign of Claudius the aureus went for 100 sestertii, or 25 silver denarii; at which rate it remained. The aureus fell by degrees to 45 in the pound, or about 110 grains of medial weight each, and continued of this standard till the time of Elagabalus, when it fell to about 92 grains at an average, or near 55 in the pound. Under Philip aurei of two or three sizes appear, of a rude fabric, and having a head of Rome on one side, and various reverses; and this practice of making different sizes of gold coins continued, so that under Valerian I., Gallienus, and his successors, five or six sizes occur. That the aureus went for 25 silver denarii down to Alexander Severus is clear, but the value of these different sizes does not appear. Supposing that standard to remain till the time of Constantine I. the double aureus will have borne 50 silver denarii, and the aureus 25. The "triens" must have had eight silver denarii, and two denarii ærei; the double triens twice as much. The denarius was not then worth above 14*s.* English. Under Aurelian and his successor Probus, the aureus was of 100 grains; and there were also halves of about 50 grains, and double aurei, upwards of 200 grains, of very fine workmanship. Down to Constantine I. the aureus stood at between 80 and 70 grains. This prince, without altering the size of the coin, introduced, instead of the aureus, the solidus of 6 in the ounce of gold, and to pass for 14 of his new

new silver coins, called Milliarenses, and 25 denarii as before; gold being to silver about 14 to 1. The solidus, or chief gold coin, continued of the same standard to the close of the Byzantine empire; for gold was common in Constantinople, while silver became more and more scarce. The solidus was worth 12s. sterling. See SOLIDUS.

In the first gold coinage at Rome, the aureus was divided into four inferior parts; the semissis, or half, of 60 sestertii; the tremissis, or third, of 40; the fourth, of 30; and the sixth, or scrupulum, of 20. But soon after all these subdivisions were discontinued, except the semissis, or half; which occurs in the consular times, and in those of some emperors, but is extremely scarce, so that few of them must have been struck. Some have supposed, without sufficient authority, that the Romans called the gold semissis a denarius aureus. Denarius was used, as our penny, for a coin. The common aureus was called denarius aureus very naturally, because it was of the same size with the silver denarius. See AUREUS.

With regard to the materials of English money, see COIN.

As for the *impression* of money, the Jews, though they detested images, yet stamped on the one side of their shekel, the golden pot which had the manna: and on the other, Aaron's rod; the Dardans, two cocks fighting; Alexander, as is held by some, his horse Bucephalus: though this may be doubted of, because the horse is found as frequently on the coins of several of the kings of Macedon, his predecessors, as his. The Athenians stamped their coins with an owl, or an ox; whence the proverb on bribed lawyers, *bos in lingua;* the people of Ægina with a tortoise; whence that other saying, *Virtutem & sapientiam vincunt testudines.* As to the Romans, the monetarii sometimes impressed the images of men that had been eminent in their families, on their coins; but no living man's head was ever stamped on the Roman coin till after the fall of the commonwealth; after that time they bore the emperor's head on one side; and, from this time, the practice of stamping the prince's image on coins has obtained among all civilized nations, the Turks and other Mahometans excepted; who, in detestation of images, inscribe only the prince's name, with the year of the transmigration of their prophet.

For an account of the impression of British money, see COIN.

As to the *figure* of money, it is either round, as in England; multangular, or irregular, as in Spain; square, as in some parts of the Indies; or nearly globular, as in most of the rest.

After the arrival of the Romans in this island, the Britons imitated them, coining both gold and silver with the images of their kings stamped on them; when the Romans had subdued the kings of the Britons, they also suppressed their coins, and brought in their own, which were current here from the time of Claudius to that of Valentinian the Younger, this being about the space of five hundred years.

Mr. Camden observes, that the most ancient English coin he had known, was that of Ethelbert, king of Kent, the first Christian king in the island; in whose time all money accounts began to pass by the names of pounds, shillings, pence, and mancuses.

The penny seems borrowed from the Latin *pecunia,* or rather from *pendo,* on account of its just weight, which, till Edward III.'s reign, contained as much silver as about three-pence of our money: these were coarsely stamped with the king's image on one side, and either the mint master's name, or the city's where it was coined, on the other: five of these pence made their scilling, probably so called from *scilingus,* which the Romans used for the fourth part of an ounce; forty of these scillings made their pound, and four hundred of these pounds were a legacy, or a portion for a king's daughter; as appears by the last will of king Alfred.

By these names they translated all sums of money in their old English testament; talents by *pundes;* Judas's thirty pieces of silver by *thirtig scillinga;* tribute-money, by *pening;* and the mite by *feorthling.*

But it must be observed they had no other real money, but pence only; the rest being imaginary monies, *i.e.* names of numbers, or weights: thirty of these pence made a mancus, which some take to be the same with a mark; manca, as appears by an old MS., was *quinta pars unciæ.* These mancas, or mancuses, were reckoned both in gold and silver; for in the year 680, we read, that Ina, king of the West Saxons, obliged the Kentish men to buy their peace at the price of thirty thousand mancas of gold. In the notes on king Canute's laws, we find this distinction, that *mancusa* was as much as a mark of silver; and *manca,* a square piece of gold, valued at thirty-pence. See MANCUS.

The Danes introduced a way of reckoning money by ores, *per oras,* mentioned in Domesday book; but whether they were a distinct coin, or a certain sum, does not plainly appear: this, however, may be gathered from the abbey-book of Burton, that twenty ores were equivalent to two marks.

They had also a gold coin called *byzantine,* or *bezant,* as being coined at Constantinople, then called *Byzantium;* the value of which coin is not only now lost, but was so entirely forgotten, even in the time of king Edward III. that, whereas the bishop of Norwich was fined a byzantine of gold, to be paid the abbot of St. Edmunsbury, for infringing his liberty (as it had been enacted by parliament in the time of the Conqueror), no man, then living, could tell how much it was; so that it was referred to the king to rate how much he should pay; which is the more unaccountable, because, but a hundred years before, two hundred thousand bezants were exacted by the sultan, for the ransom of St. Lewis, of France; which were then valued at one hundred thousand livres.

Though the coining of money be a special prerogative of the king, yet the ancient Saxon princes communicated it to their subjects; insomuch, that in every good town there was, at least, one mint, but at London eight; at Canterbury four for the king, two for the archbishop, one for the abbot at Winchester, six at Rochester, at Hastings two, &c.

The Norman kings continued the same custom of coining only pence, with the prince's image on one side, and on the other the name of the city where it was coined, with a cross so deeply impressed that it might be easily parted, and broken into two halves, which, so broken, they call *halfpence,* or into four parts, which they called *furthings,* or *farthings.*

In the time of king John, money coined in the east parts of Germany came in special request in England, on account of its purity, and was called *easterling money,* as all the inhabitants of those parts were called *Easterlings;* and shortly after, some of those people, skilled in coining, were sent for hither, to bring the coin to perfection; which, ever since, has been called *sterling,* from *easterling.*

King Edward I. who first adjusted the measure of an ell by the length of his arm, herein imitating Charles the Great, was the first, also, who established a certain standard for the coin, which is expressed to this effect by Gregory

gory Rockley, mayor of London, and mint-maſter. "A pound of money containeth twelve ounces: in a pound there ought to be eleven ounces, two eaſterlings, and one farthing, the reſt alloy: the ſaid pound ought to weigh twenty ſhillings and three-pence in account and weight; the ounce ought to weigh twenty-pence, and a penny twenty-four grains and a half. Note, that eleven ounces two-pence ſterling ought to be of pure ſilver, called *leaf-ſilver;* and the minter muſt add, of other weight, ſeventeen-pence halfpenny farthing, if the ſilver be ſo pure."

About the year 1320, the ſtates of Europe firſt began to coin gold; and, among the reſt, our king Edward III. The firſt pieces he coined were called *Florences*, as being coined by Florentines; afterwards he coined nobles; then roſe nobles, current at ſix ſhillings and eight-pence; half-nobles, called *halfpennies*, at three ſhillings and four-pence, of gold; and quarters at twenty-pence, called *farthings of gold*. The ſucceeding kings coined roſe-nobles, and double roſe-nobles, great ſovereigns, and half Henry nobles, angels, and ſhillings.

King James I. coined units, double crowns, Britain crowns; then crowns, half-crowns, &c. On this ſubject, ſee MEDALS.

1 W. & M. Queen Anne George I. George II.	I do not find any alteration in the standard of the gold or silver down to the present time. 22 carats fine and 2 alloy are the lb. of gold, and 11 oz. 2 dwt. fine, and 18 dwt. alloy, the standard lb. of silver; and the division of the pound of gold continues the same; that is to say, into 44½ guineas, and the silver into the usual number of crowns, &c. But the guineas have varied in the nominal value several times, rising up to XXX*s.* and declining to XXI, the present current value; but never have been reduced again to their intended level of XX*s.*, nor indeed ought, when compared with the Portugal pieces of 3*l.* 12*s.*, 1*l.* 16*s.*, the guinea appears to be better worth XXI*s.*							15 21

			To the lb. Troy.	
Portugal	-	£3 12 -	13	£46 16 0
English guineas		1 1 -	44½	46 14 6
				0 1 6
And the Portuguese standard worse ¼ grain				0 2 6
Total worse lb. troy by standard and tale			-	0 4 0

This, and the difference in point of exactness in coining, wherein the Portugal is much more defective than the English coins, may be very good reasons for their being refused in payments in any of the receipts of the public revenue; but answer very well the purpose of those who benefit by the irregularity, in trading with the heavier, and passing off the lighter by tale; and which, if they can turn into guineas or heavy silver, make another gain.

How our standard is proportioned to that of other countries, and thence what the true par of exchange is between us, see COIN.

A TABLE exhibiting the Standard, Weight, Value, and comparative View of English Gold Money from King William I., A.D. 1066, to King George III. A.D. 1764.

Years of the kings' and queens' reigns, or the dates of the several mint indentures.		Standard of the gold at each period. Fine gold.			Alloy.			Value or number of pounds, &c. the lb. troy of stand. gold has been coined into.			Value or number of pounds, &c. the oz. troy has been coined into.			Value of 20 shillings of coined gold at each period of our present money.			Proportion of the same 20 shillings to our present 20 shillings.	Proportion between the current value of the lb. troy of standard silver and standard gold.	Proportion of fine silver to fine gold at each period.

A TABLE, fhewing the ftandard Weight, Value, and comparative View of Englifh Silver Money, from King William I. A. D. 1066, to A. D. 1765.

Dates of the feveral Mint indentures.	Standard of the filver at each period. Fine Silver.	Alloy.	No. of fhillings &c. in the pound weight, viz. in twelve ounces troy, of ftandard filver coined at each period.	Weight of twenty fhillings in reckoning of ftandard filver at each period.	Weight of fine filver contained in twenty fhillings at each period.	Value of the fame twenty fhillings in reckoning of our prefent money.	Proportion of money at each period to that of our prefent money.	Value of the ounce of the then ftandard filver to that of our prefent money.	Value of the ounce fine filver at each period.	Kings and queens in thefe periods.

For tables containing the principal gold and filver coins of all nations: the firft table fhewing the finenefs of thofe of gold, compared with the Englifh ftandard of 22 carats, with their weight, and contents in pure gold, and their value, according to the mint price of gold in England, *i. e.* 3*l.* 17*s.* 10½*d. per* ounce, ftandard; and the fecond table exhibiting the finenefs of all filver coins, compared with the Englifh ftandard of 11 oz. 2 dwts., their weight and contents in pure filver, with their value according to the mint price of filver in England, *i. e.* 5*s.* 2*d. per* ounce, ftandard; we refer to the valuable publication of Dr. Kelly, entitled "Univerfal Cambift."

The

The king, by proclamation, may at any time prohibit all his subjects, not exceeding one year, to lend or advance money to any foreign prince or state, without licence under the great or privy seal; and if any person knowingly offend in the premises, he shall forfeit treble the value of the money lent, &c. two-thirds to the king, and the other to the informer; but persons may deal in foreign stocks, or be interested in any bank abroad, established before issuing his majesty's proclamation. Stat. 3 Geo. II. cap. 5.

Money, taking the term in its most comprehensive sense, may be defined to mean any commodity that can be employed for the purpose of facilitating the interchange of what men possess for what they desire.

In the science of political economy, discussion is much retarded and perplexed, by the loose and ambiguous meaning of the terms employed, and by the want of introductory and preparatory axioms: the terms used in this science have, in the common concerns and language of life, acquired certain meanings so firmly, that it is difficult to shake them loose and forget them, when we come to employ them in it. The consequence is, that the reader, not aware that words, the meaning of which is familiar to him, are to be taken, in the discussion on which the author has entered, in a new and peculiar sense, is startled and thrown back into doubt and confusion, when, after having followed the train of reasoning for some time, and admitted its justness and force, he finds that he and the author have throughout it been affixing very different meanings to the same terms. The same perplexing consequences result from the want of introductory and preparatory axioms: perhaps every science would be benefited as well as mathematics, though not to such a degree, if the terms to be employed were previously defined, and the positions to be taken for granted were previously laid down. It is certain that thus the way would be cleared at the commencement, and this every person conversant with subjects which require a long and intricate train of reasoning knows to be of the utmost importance towards the attainment of the truth.

These observations are introduced to apologize for, or rather to warrant the time that may be occupied in pursuing the justness and accuracy of the definition given of money, and in pointing out the erroneous and defective character of some other definitions, before entering on the subject itself.

Hume, in his Essay on Money, has defined it to be "the instrument which men have agreed upon to facilitate the exchange of one commodity for another." At first sight it may seem that this definition of Hume, and that which stands at the head of this article, are precisely the same; they, no doubt, are very similar; and if precision and fullness were not absolutely indispensable in all definitions, and if political economy, as has been already remarked, did not more than most other sciences, require this fullness and precision, Mr. Hume's definition must have been adopted as sufficiently accurate. But on examining it we shall find, that, taking it strictly (and a definition, if it will not bear to be taken strictly, loses its essential character and its whole utility), it does not comprehend money, when employed to interchange labour and skill for commodities. In all cases where one commodity is exchanged for another commodity, and an instrument is employed for the purpose of facilitating that exchange, that instrument, according to Mr. Hume's definition, is money; but if we adhere strictly to his definition, the facilitating of no exchange except of one commodity for another is effected by money; or rather, Mr. Hume's definition does not comprehend any other kind of exchange, except that of one commodity for another, and here he does not comprehend all the uses of money, or employs the term *commodity* in a sense not generally known and admitted: in either case it is objectionable; in the first, because there are instances of interchange which it does not comprehend, and in the second case, because it employs a term in a meaning not known and acknowledged.

After all, however, Mr. Hume's definition of money approaches much nearer the truth than those which are commonly given. According to some, money may be defined to be the standard of value. Here another source of error and confusion opens to our view: in all scientific discussions, metaphorical language, or terms borrowed from other subjects, if not employed with great caution and judgment, are very prejudicial: they either leave no distinct idea when transformed from their appropriate subjects, or more frequently carry with them more of their original meaning and force than the subject to which they are applied will admit of. If we examine the phrase standard of value, without at present enquiring how far it is a proper definition of money, we shall find that it gives no distinct idea: the word standard is here employed in a meaning perfectly different from that which is given to it, in subjects where it is a common and appropriate term. If we were to talk of the standard of weight, of height, or of fineness, we should be immediately struck with the expression as conveying no meaning, as, in fact, nonsense: it is well known what a standard weight, height, or fineness are; they mean a weight, height, or fineness fixed by law or custom. Standard of value, therefore, as applied to money, cannot define it, because, if examined, it will be found to convey no meaning: and if the terms be altered, and "standard value" used in their stead, though these words convey a meaning, it is a meaning which cannot be applied to them, if employed as a definition of money. Money cannot be said to be the standard value of commodities: if the price of any commodity were fixed by law, suppose, for instance, that the price of a bushel of wheat were fixed at one guinea, then this coin, this description of money might be said to be the standard value of a bushel of wheat; but in no point of view can money, generally speaking, be said to be the standard value of commodities; and we have shewn that the expression standard of value has no meaning.

It perhaps may be thought that more time has been occupied in pointing out the absurdity of this definition than was necessary; but in political economy, as much is to be done by removing error, as by establishing truth: when error is completely removed, so that the way is clear and open, common sense will do much in this branch of science.

The next definition of money is much more plausible: those who are aware, either of the absurdity, or who suspect the incorrectness of the former definition, maintain that money is the measure of value. In our remarks on that definition which made money the standard of value, it was not deemed necessary to investigate the proper meaning of the word *value*, because the remarks that were offered on the other term were deemed amply sufficient to set it aside. But on examining this definition, both the terms must be scrutinized.

Smith, in his Wealth of Nations, has observed that every commodity has two sorts of value, a value in use and a value in exchange; but in political economy the term *value* can have only one meaning. Political economy relates only to a state of society, where a division of labour exists; where, of course, each man has more of the commodities his labour and skill have produced than he has occasion for, and consequently wishes to exchange them for commodities produced by the labour and skill of others. Where no division of labour exists; where there is, consequently, no interchange of commo-

commodities; there is, ſtrictly ſpeaking, no wealth, no value; there is no room, no occaſion for the ſcience of political economy. Whether, in treating of other ſubjects, *value* ſhould or can be uſed in a ſenſe different from that which is given it in political economy, as a ſcience relating to the interchange of commodities, is a queſtion foreign to the preſent diſcuſſion. In political economy, and under the circumſtances of ſociety, which political economy ſuppoſes and refers to, *value* ought only to be employed in one ſenſe. What that ſenſe is a little reflection will teach us.

In the ſtate of ſociety we are ſuppoſing commodities are interchanged: before this can take place, the quantities or weights of each commodity that are to be given for any other commodity, muſt be fixed; and that particular weight or quantity of any given commodity, which can be obtained for a certain weight or quantity of another commodity, may, ſtrictly ſpeaking, be ſaid to be the value of this ſecond commodity: it avails or has power to obtain the former commodity. But this expreſſion may be reciprocally uſed: if, for inſtance a buſhel of wheat is exchanged for 30lb. of meat, the value of the buſhel of wheat may be ſaid to be 30lb. of meat, and the value of 30lb. of meat to be a buſhel of wheat. Value, therefore, is a term which, in political economy, has, properly ſpeaking, only one meaning, becauſe this ſcience relates ſolely to a ſtate of ſociety, where interchange of commodities takes place: and this meaning of the word value, referring to the interchange of commodities, implies that where any two commodities are interchanged, each can procure a certain portion of the other.

Let us now revert to the definition of money under conſideration: according to it, money is the meaſure of value. The expreſſion, at firſt ſight, ſeems ſufficiently preciſe and clear, whatever opinion may be formed of its propriety and juſtneſs as a definition of money. But a cloſer inſpection and examination of it will probably convince us that it is not ſo preciſe and clear as at firſt ſight in ſeems to be. When we talk of a yard as a meaſure of length, we have preciſe and clear ideas affixed to our expreſſion: we mean, that if ſuch a table is a yard long, we can immediately not only figure to ourſelves its length, but compare it with other objects which poſſeſs length. How will this apply to money defined and conſidered as the meaſure of value? Whoever knows what a yard is, immediately and clearly knows what is meant by a yard of cloth; but he who equally well knows what an ounce of gold, or a guinea is, by no means, therefore, certainly knows what quantity of corn, or any other commodity, this ounce of gold or guinea will meaſure. Indeed the very application of the term *meaſure*, as applied to value, when thus brought forward in a particular caſe, and not uſed generally and looſely, muſt ſtrike us as improper, and contrary to analogy. We have ſeen what is the meaning of the term *value;* it expreſſes the quantity of any particular commodity which can be procured in exchange for another commodity:—in order to do as much juſtice as poſſible to the definition of money, under conſideration, let us take money as one of the commodities, and corn as another; we ſhall ſtill perceive that the definition is incorrect. How can money be ſaid to meaſure the value of corn? It has been obſerved, that value is a reciprocal expreſſion; that is, it can be equally well applied to either of the two commodities, which are interchanged for each other: if money, therefore, may be defined to be the meaſure of the value of any commodity, of corn for inſtance; corn, with equal propriety, may be defined to be the meaſure of the value of money. But in neither caſe can the definition be uſed; for nothing changeable in value, that is, which at one time will command a greater or leſs quantity of any commodity than at another time, can meaſure value.

It may, perhaps, be urged, that if the term were changed, and if money were defined to be the expreſſion of the value of commodities, the objection would be removed: there is ſome weight and propriety in this remark: value muſt have reference to two commodities: it muſt expreſs how much of any particular commodity can be obtained for another commodity; and as money is uſed as that commodity, for which all others are directly given in exchange, the value of all others would naturally be expreſſed with reference to money. But ſtill this would be a very incomplete definition of money; and when we come to enquire how money (according to the definition given at the head of this article) facilitates the interchange of what men poſſeſs for what they deſire, we ſhall find that this definition includes the former.

Let us now inquire what qualities money muſt poſſeſs, in order that it may anſwer the purpoſe pointed out in the definition; *viz.* that of facilitating the interchange of what men poſſeſs for what they deſire. Money, it has been ſaid, being the meaſure of value, muſt have value, on the ſame principle and for the ſame reaſon, that whatever meaſures length muſt have length. It may be true that money muſt have value; but not for the reaſon (if reaſon it can be called) here alleged. This mode of reaſoning affords another inſtance of the bad effects of borrowing illuſtrations and proofs in political economy from other ſubjects. At firſt ſight, the concluſion that money, being the meaſure of value, muſt have value, appears to follow neceſſarily from the facts brought forward in ſupport of it; though thoſe facts are merely analogous, and not belonging to the ſubject to be proved; but it requires only a little time for reflection, it merely requires that the judgment ſhould have time to withdraw itſelf from the influence of powerful but irrelevant aſſociations, in order to perceive that there is no force in the remark, that becauſe what meaſures length poſſeſſes length, therefore what meaſures value (allowing the expreſſion) ſhould poſſeſs value.

There is, in fact, not the leaſt occaſion for bringing in this analogy to prove that money, in its character of money, muſt poſſeſs value: that is implied in the very meaning of the term; nothing can facilitate the interchange of commodities; nothing can be exchanged itſelf for any other commodity which does not poſſeſs value. But a much more important and difficult queſtion remains to be noticed, diſcuſſed, and ſolved. Is it eſſential to the character and uſes of money that the commodity of which it is formed ſhould poſſeſs value, independent of its application as ſuch? Another queſtion ariſes out of this, or rather is involved in it. Can the value of any commodity, when uſed as money, be greater than it poſſeſſed when not applied to this purpoſe?

In order that theſe intricate and important queſtions may be conſidered with due deliberation, on ſufficient data, and in regular order, it will be proper to call in the aid both of ſpeculative reaſoning, and of what we know to be fact. Our acquaintance with the hiſtory of nations, at that period when they firſt began to perceive the neceſſity of adopting ſome inſtrument of barter, is ſo very imperfect, that we are not ſupplied with a detail of the different methods they purſued previous to the adoption of the metals for that purpoſe: it is eaſy to imagine, however, how they would proceed: and by the help of what we actually know to have been the caſe, and of what we may fairly conclude to have been the intermediate ſteps, where hiſtory is ſilent, we may gain the point we have in view; *viz.* an anſwer to the queſtions, whether it is eſſential to the character and uſes of money, that the commodity of which it is formed should possess value, independent of its application as such; and whether the value of any commodity, when used as money, is greater than it possessed when not applied to this purpose. All history coincides in informing us that the commodities first used as money possessed value prior to, and independently of, their being invested with this character. Cattle appear to have been used for this purpose at as early a period of history as we can trace back; and when the metals were first employed, those kinds were chosen which were in regular use and demand, and which, consequently, possessed value. Indeed it is natural to suppose, that if a person could not, in exchange for the produce of his labour, procure directly what he wanted, he would dispose of it only for such a commodity as he knew was in general demand, and which, therefore, he could be at no loss to dispose of. Unless we can imagine that men would barter their commodities for what they neither needed at the moment, nor what, at some future period, would procure them what they needed, this must have been the case. Let us suppose that a person, in this state of society, had more corn than his own wants required; and that another person stood in need of this corn, but had only some commodity to offer in exchange for it, which the first person did not then require: if this commodity were of such a nature, as the first person were likely soon to require, or if it were such as he knew was in demand, and would, therefore, be the certain means of obtaining him any other commodity which he might wish for, he would have no objection to exchange his corn for it. But it is evident, that in both these cases the exchange is that of commodities that are valuable; *i. e.* each of which avails to purchase or procure some other useful and desirable commodity. In the latter case, where the exchange of the corn was made for a commodity which was to be employed again in exchange, that commodity, in fact, was money: it answers exactly to the definition of money, it facilitates the exchange of commodities: the person who possessed the corn, wished, for instance, to exchange it for meat; but the person who was disposed to take his corn, and to whom, at that period, we could suppose he could alone dispose of it, had no meat; he, therefore, offered him some other commodity, and if this commodity would avail, either by direct or indirect exchange, to procure meat, the person possessing the corn would not hesitate to part with the one for the other. But it is plain, that unless this commodity would avail to obtain, either directly or indirectly, the meat which he needed (or whatever else it might be), the person could not part with his corn. Money, therefore, or that commodity which is employed for the purpose of facilitating the exchange of what men possess for what they desire, must possess value, at least when first used in that character.

It still, however, remains to be inquired, whether a commodity used as money, and, as such, possessed of value, when first employed for that purpose, may not retain its character and power of money, when deprived of its property of value. As the metals are now used for money, let us suppose that gold and silver were to lose all value, independently of their character as money; that there was no demand for them as articles of luxury or use:—would they still be as valuable as money? It would, at first sight, appear certain, that as they had derived their power as money solely from their being valuable commodities, when they were stript of their value, they would at the same time be necessarily stript of their character of money. But this may be doubted, both from what we know of the human mind, and from what actually takes place. Men, having been so long accustomed to receive gold and silver in exchange for their commodities; and having so long ceased to revert to, or consider on every occasion of parting with their commodities for these metals, that they were receiving something in exchange intrinsically valuable; *i. e.* valuable independently of its character of money; would, by the mere force of habit and association, and by the confidence which they had produced, continue to receive gold and silver, even after their intrinsic value had ceased; *i. e.* after they had lost that property which at first had made them pass as money. This we see partly to be the case: men do not hesitate to receive coin that is much worn; or, in other words, they exchange their commodities for coin, after it has lost part of its value; and the habit and association are much more likely to be broken, by a diminution in the size, or an alteration in the appearance of the coin, while the value of what is actually received remains the same, than by receiving coin in exactly the same state as usual, only that the metal of which it is made has lost its intrinsic value.

We may therefore infer, on this part of the subject, that no commodity can be employed at first as money, unless it possess value; that any circumstance which affects this value, will, for a very considerable time, affect the character and credit of the commodity as money; but that, in process of time, the consideration of the intrinsic value of the commodity loses much of its force, and it is taken as money without reference to this intrinsic value.

In one respect, however, the value of money would fall, if the commoditiy of which it were formed lost its intrinsic value; *i. e.* if it no longer were in demand for any other purpose but that of money. Let us suppose that the demand for gold and silver, except for the purpose of money, suddenly ceased: the natural and immediate consequence would be, that what was before used for articles of luxury, &c. would be coined into money; and the quantity of money being thus increased, its value would necessarily fall. The other question that was started, *viz.* can the value of any commodity, when used as money, be greater than it possessed, when not applied to this purpose; has, in a great measure, been solved in the observations already made. In all cases where worn coin is taken, this is, in fact, the case. It may, indeed, be urged, that worn coin, only of the inferior metals, is received at its original value; that gold coin is not so received; and that in the instances where silver coin, when worn, is received at its original value, it is only so received as part of the gold coin. But as there can be no doubt of the fact, that the value of twenty-one worn shillings, when compared with the value of a guinea, is much less than the value of that quantity of silver which would form twenty-one mint shillings, when compared with a guinea, the inference is indubitable, that in all cases where worn silver coin is received either for commodities, or for gold coin at its original value, the value of silver used as money is greater than its value as a simple commodity.

The inference which has been drawn, however, from this circumstance is by no means correct;—that money does not derive its character from the intrinsic value of the commodity of which it is formed, nor from the general confidence resulting from the knowledge of that value, and the consequent willing, and habitual acceptance of it in exchange for all commodities; but from authority. Those who are of this opinion, contend that the stamp on the coin gains it a ready circulation, not because it proves its legal weight and purity, but because it is the sign of the authority of government; that in receiving money no regard is paid to the material of which

which it is formed, nor to the value of that material, but solely to the authority which issued it. If this were true, the same authority could make stamped leather pass as current as stamped gold and silver. But this opinion is grounded entirely on a misconception of the nature of money, and of the manner in which any given commodity is invested with that character; it also confounds two things quite distinct and unconnected. There can be no doubt that government, or any body of men, who receive a large portion of the wealth of the community, could give a partial circulation to any kind of money, independently of its intrinsic value, by declaring their readiness to receive it in payment of their demands. In Scotland, and in the provincial districts of England, where local bank notes are common, confidence and circulation are often given to them in a great degree, by the declaration of the agents of government, that they will receive them in payment of the different taxes; but this is not authority: this mode of giving circulation to any kind of money is merely an illustration of the doctrine that has been laid down in this article; that the reason why any commodity, when originally employed as money, should possess intrinsic value, is, that thus it will be readily and generally received; but if this ready and general acceptance can be given any other way, the purpose is effectually answered. In a rude state of society, the only mode of ensuring this was, to offer some commodity in general use and demand; and therefore when a person parted with the produce of his labour, if he could not get for it what he wanted, he selected, and kept by him, some commodity which would always ensure the obtaining of the object of his wishes either directly or indirectly. In a more advanced state of society, confidence would effect the same object; but there is a great difference between authority and confidence; there is a great difference between commanding that any commodity should be received as money, and declaring that it will be received as such. The former mode, we know from history, has always failed of success, whenever the command was not supported by the intrinsic value of the commodity ordered to pass as money. The latter mode, if the declaration came from those through whose hands a great portion of the money of the country must pass, will give credit and circulation as money to any commodity, nearly with as much facility and certainty; though not to such an extent, as if the commodity possessed intrinsic value equal to that at which it was issued as money.

Money, then, or any commodity which can be employed for the purpose of facilitating the interchange of what men possess, for what they desire, must, in the first instance, have possessed intrinsic value: if this intrinsic value were lessened, before its character and use, as money, had become so firmly fixed, as to have superseded or effaced, in commercial transactions, all reference to its intrinsic value, then the value of it, as money, would fall in proportion as its intrinsic value were lessened. But this would not be the case, at least so certainly, and in such exact proportion, if the lessening of the intrinsic value took place in a country of great commerce and confidence, in a gradual manner, and by no means that were calculated to create alarm or distrust.

The next topic, in point of order and importance, connected with the consideration of the principles of money, is suggested, and will be best explained by a passage in the essay "Of Money" by Hume, already referred to. "It was a shrewd observation of Anacharsis the Scythian, who had never seen money in his own country, that gold and silver seemed to him of no use to the Greeks, but to assist them in enumeration and arithmetic." In this sentiment of Anacharsis, we may perceive the germ of the opinions of those authors, who maintain either what they call the doctrine of an abstract currency, or that money is but counters wherewith to reckon the different commodities that are mutually exchanged in the concerns of life; and it is also worthy of remark, that the mode in which the use of money is supplied in London and all commercial cities, where observation and experience have suggested expedients for it, is exactly that which Anacharsis supposes to have been the only mode, in which gold and silver were of use to the Greeks. Our modern merchants, in many of their transactions, merely set off the value of one commodity against the value of another; this they indeed do by rating the value in their books by pounds, shillings, and pence, but real money is not used in the transaction. But to return to the consideration of the more immediate and relevant topic suggested by the remark of Anacharsis. If gold and silver were of no use, but to assist in numeration and arithmetic, as he directly maintained; and as those who regard it only as counters, virtually maintain; or if the real currency of a country could be only an abstract currency; then the value of this money or currency could not vary, except by a variation in the supply of commodities; for, confining ourselves at present to the doctrine which represents money only as counters, it is evident that they must always bear the same proportion to the commodities (provided, as before remarked, that the supply of commodities did not vary) which they served to rate or estimate, in the same manner as if all exchanges of commodities were effected by the mode adopted in London for many of them, the only circumstance which could make any difference in the value at which they were respectively rated in the books of the merchants, would be a variation in the supply; for if money were only counters, and of no use but to assist in numeration and arithmetic, there would be no motive to increase the quantity of it, and consequently any variation between the supply of it and of commodities, must arise from a greater or less supply of the latter. The inference, that any difference in the value of money, or the command it possesses over commodities, must arise from a variation in the supply of the latter, follows more directly and necessarily from the doctrine of an abstract currency. It is, however, so very difficult to conceive of such a currency, and therefore to reason upon it, that very few observations may suffice. Those who maintain it seem to confound two things; the name and denomination, and the power of the currency; and to infer, because the former may be considered as something abstract, therefore the latter is so also; that because the former remains the same, therefore there is no change in the latter. If, however, by abstract currency, they mean money of account, (and that seems the only clear meaning that can be affixed to the terms,) then the observation just made holds perfectly good; that if there were no other money but money of account, or abstract currency, any variation in the power or value of this, when compared with commodities, must proceed from a change in the supply of the commodities; for it is impossible that mere abstract currency, or money of account, not having actual existence, can vary.

But money is of some other use than merely to assist in numeration and arithmetic; and this leads us to the consideration of it, not merely in the character of a commodity which can facilitate the interchange of what men possess for what they desire—though that is the essential character of it; but as the source of industry, skill, and enterprize, and consequently of real wealth. Mr. Hume, remarking on the observation of Anacharsis, says, "It is indeed evident that money is nothing but the representation of labour and commodities, and serves only as a method of rating and estimating them.

them. Where coin is in greater plenty, as a greater quantity of it is required to represent the same quantity of goods; it can have no effect either good or bad, taking a nation within itself, any more than it would make an alteration in a merchant's books; if, instead of the Arabian method of notation, which requires few characters, he should make use of the Roman, which requires a great many. Nay the greater quantity of money, like the Roman characters, is rather inconvenient, and requires greater trouble both to keep and transport it;" it is not however perfectly correct to say, that, taking a nation within itself, a greater plenty of coin can have no effect, either good or bad; and indeed Mr. Hume afterwards points out some effects both good and bad, which a greater supply of coin produces. One effect, however, he does not advert to, which is of so injurious a nature, that if it were not generally, and in a great degree counterbalanced by the beneficial consequences of this greater supply, it would render it a most serious evil. If, where coin is in greater plenty, a greater quantity of it is required to represent the same quantity of goods; then the power of all those who possess only money, over those goods, must be diminished. We must therefore look to the other consequences of a greater supply of money.

These Mr. Hume has detailed, but the order and manner in which he supposes them to flow, is by no means correct, or warranted by facts. As this is a most important and interesting topic, it will be necessary to quote his observations, before we proceed to point out their error.

"Though the high price of commodities be a necessary consequence of the increase of gold and silver, yet it follows not immediately upon that increase, but some time is required before the money circulates through the whole state, and makes its effect be felt on all ranks of people. At first no alteration is perceived; by degrees the price rises, first of one commodity, then of another, till the whole at last reaches a just proportion with the new quantity of specie which is in the kingdom. In my opinion it is only in this interval or intermediate situation between the acquisition of money and rise of prices, that the increasing quantity of gold and silver is favourable to industry. When any quantity of money is imported into a nation, it is not at first dispersed into many hands, but is confined to the coffers of a few persons, who immediately seek to employ it to advantage. Here are a set of manufacturers or merchants, we shall suppose, who have received returns of gold or silver for goods which they sent to Cadiz. They are thereby enabled to employ more workmen than formerly, who never dream of demanding higher wages, but are glad of employment from such good paymasters. If workmen become scarce, the manufacturer gives higher wages, but at first requires an increase of labour; and this is willingly submitted to by the artizan, who can now eat and drink better, to compensate his additional toil and fatigue. He carries his money to market, where he finds every thing at the same price as formerly, but returns with greater quantity and of better kinds, for the use of his family. The farmer and gardener, finding that all their commodities are taken off, apply themselves with alacrity to the raising more, and at the same time can afford to take better and more clothes from their tradesmen, whose price is the same as formerly, and their industry only whetted by so much new gain. It is easy to trace the money in its progress through the whole commonwealth, where we shall find that it must first quicken the diligence of every individual, before it increases the price of labour."

Now there are three positions maintained in this illustrative reasoning, the first of which may, or may not, be true, according to circumstances; the other two cannot be true under any circumstance. It is assumed that the price of labour will not be increased, in the first instance, by an increase in the quantity of money, because a greater number of workmen will be employed; and of course the number of workmen thus increased, bearing the same proportion to the increased money, that they formerly did, no addition will be made to the price of labour; this, however, cannot be the case, unless we suppose that before the increased quantity of money gave employment to these workmen, they were entirely unemployed; for if they were previously employed, the greater demand for them, occasioned by the increase of money, must undoubtedly and necessarily raise the price of labour. Again, Mr. Hume supposes that the workmen who have thus gained employment, find every thing in the market at the same price as formerly, though an increased demand for the commodities sold there is necessarily occasioned by the increased money these workmen carry to market. If the price of commodities in the market is not increased immediately on the increase of demand for them, when, or how, can it be raised? not afterwards, for, as Mr. Hume justly observes, the farmer and gardener apply themselves with alacrity to raising an additional supply; and if the price was not raised, when there was only the usual supply, and a more than usual demand, it must fail when the supply is raised proportionally to the demand. The same remarks may be applied to the third position laid down by Mr. Hume, *viz.* that the farmer and gardener, though they go to their tradesmen with more money in their pockets, and can therefore afford to buy better, and more clothes than formerly, yet get them at the old prices.

In fact, the process by which an increase of money in any country promotes industry and raises prices, varies according to circumstances: if the increased supply is brought in by those who lay out money principally or entirely in consumption, the process goes on in one mode; if the increased supply is brought in by those who lay out money principally for the purposes of production, the process goes on in another way. In the first instance, the persons into whose possession the increase of money has come, naturally lay it out according to their fancies and habits, either in obtaining a larger quantity of those commodities which they formerly bought, or in the purchase of other commodities which their inferior means hitherto prevented them from obtaining: in either case there is a greater demand in the market while the supply is the same. If, for instance, the increased money comes into the possession of labouring men, they either lay it out in getting more bread for themselves and families; or if they previously had enough of that, but could not procure meat, the increased money is laid out in the purchase of meat. In the one case there is a greater demand for bread, in the other for meat; while the supply is the same: a rise in price must therefore take place. The next step in the process is that the bakers or butchers, finding a greater demand for their articles, and obtaining consequently a higher price for them, are induced to increase the supply: here then we may suppose the increased money and the bread or meat to have balanced each other. But we must look a little farther; the baker or the butcher, in the first instance, obtaining a higher price for their commodities, and subsequently selling a greater quantity, and thus increasing their profits, are enabled, in their turn, to do what the labouring men did when they obtained more money. They can afford to spend more; (for at present, all the cases we suppose are those of men who lay out their increased money in consumption, not in production); the articles on which they spend their increased profits must in their turn experience a rise of price, which will produce a greater supply. It is needless to pursue

sue the operations of this additional supply of money any further, or to point out how it will be gradually spread over the community, always in some degree affecting the prices of those commodities to the purchase of which it is applied. It may, however, be further remarked, that there are many disturbing forces, which may prevent the consequences now enumerated from following certainly, and in the order laid down, from an increased supply of money; and that the rise of price is seldom or never proportioned exactly to the increased demand; while, on the other hand, a supply equal to the increased demand seldom brings the prices down to their former level.

Let us now suppose that the increased quantity of money is in the possession of those who will expend it in productions; some individual case will render the subject more clear, and enable us to trace the consequences more directly and minutely. A cotton manufacturer, for instance, has his capital doubled, and determines to apply this increase of fortune solely to the extension of his trade: of course he must employ more men to work for him, and more of the raw material. Unless we can imagine that there were quite unemployed the additional number of men that he would need, his demand for more workmen must raise the price of labour; and even on the supposition that there were a sufficient number of unemployed workmen, still, if we reflect a little, we must be convinced that the price of labour will be raised, even in this case; for these unemployed workmen, being of course anxious to procure employment, may be considered as a supply greater than the demand in the market; of course this circumstance must have a considerable effect in lowering the price of labour; but when the cotton manufacturer hires them, he in fact increases the demand for workmen, and therefore must raise the price. So that the effect is not altered in its nature, though it is in degree, whether we suppose the cotton manufacturer to go into the market for workmen, where all are already engaged, or where there are a sufficient number to be found unemployed: in the former case, the price of labour would rise much higher than it would in the latter case; for we are to reflect that the lowering of the price of labour or of any commodity is effected, not only by those who want it not being so numerous, or not being so able and willing to purchase it at the former price, but also, in nearly an equal degree, by those who have it to dispose of, on their perceiving the demand diminished, offering it at a lower rate, each being anxious, under these circumstances, to get rid of the article he has in the market.

The first effect, then, of the increased capital of the cotton manufacturer is to raise the price of labour: it is unnecessary to point out again how the increased wages which the labourer obtains will operate on the price of commodities, and subsequently on their supply; this has already been done. But besides a rise in the price of labour, the increased capital of the manufacturer, being partly expended on cotton, and partly also on the buildings and machinery necessary to manufacture this additional quantity of cotton, its effects on these must also be apparent, at first in the rise of price, and afterwards in the greater supply. On the other hand, the supply of cotton goods in the market being increased, while the demand remains the same, the price of them must fall: here then we may perceive an essential difference between the effects of an increased supply of money, accordingly as it comes into the hands of those who lay it out in consumption, or into the hands of those who lay it out in production. In the latter case, the immediate effect is a rise in price, the indirect and subsequent is a greater supply, stimulated by this rise in price; but this greater supply may not be more than sufficient to meet the greater demand; in the former case, although a rise in the price of labour, and of those articles necessary for the manufacture is occasioned, which is also met by a greater supply; yet, besides these effects corresponding to the effects in the latter instance, there is a greater supply of cotton goods in the market; so that whatever opinion may be formed respecting the consequences (as they affect the national prosperity) of an increased supply of money in the hands of those who expend it in consumption, there seems to be no reason for doubting that the consequences are beneficial, when the increased supply is expended on production.

But it will be proper to look more closely into the effects of a greater quantity of money, in order to perceive in what case it is beneficial to a nation, and by what means it is beneficial; and in what cases it is prejudicial to a nation, and by what means it is so.

When the effect of a greater supply of money is to stimulate industry, so as to bring a greater quantity of commodities into the market, then there can be no doubt that it is beneficial to a nation. At first sight it may appear of little moment, whether there is a greater quantity of commodities produced or not, if the price of them is not diminished: but the real wealth and prosperity of a nation does not consist in there being few commodities produced, though they are sold at ever so cheap a rate; it consists in the abundant supply, provided there is a demand for that supply, whatever be the price of them; for an abundant supply and a proportional demand proves that all classes of the community have full employment; that they are exerting their skill and industry, and that this skill and industry are well paid. Now there is no motive which will stimulate men so powerfully and generally to the exertion of additional skill and industry, as the prospect of greater gain; and the prospect of greater gain cannot be held out, unless there is a greater demand for their goods, and a consequent higher price given for them; this, it is evident, cannot be the case, unless the quantity of money in the nation be increased. It may, indeed, be alleged, that a greater demand for any particular commodity may be created by the abstraction of demand for some other commodity; but in this case it is evident, that what is gained to the nation in one case, is lost in the other; for those who produce the latter commodity will suffer from the diminution of demand, as much as those who produce the former commodity will be benefited by an increase of demand. The case supposed, therefore, must be that of a greater demand for any particular description of commodities, without any variation in the demand for any other commodity; and this case cannot exist, unless there be a greater quantity of money in the nation.

This illustration of the effects of an increased quantity of money has proceeded on the supposition that they were confined within the nation where the increase took place: but it may be proper to examine what will be the effects on the commercial transactions of this nation with other nations: these effects will be similar to those which are known to proceed from great capital; *i. e.* the ability to purchase the raw materials of manufacture cheaper, by taking them in greater quantities, and for ready money, and to sell the manufactured article cheaper, both from the circumstance of the raw materials having been bought cheaper, and from the increase of capital, and consequently of trade, enabling the manufacturer to be satisfied with less proportional profits. It is evident, however, that all these beneficial consequences depend on one important circumstance; that the increased quantity of money, on whatever it is expended, though it at first raises the price, yet soon afterwards, by stimulating induftry, brings in fuch an additional fupply, as fully anfwers the increafed demand. In this cafe alone money, when it flows with greater abundance than formerly into a nation, is beneficial to it.

A greater abundance of money will be prejudicial to a nation, either when it flows in too rapidly or irregularly; or when the nation, previoufly to this additional fupply of money, had exerted its induftry and fkill to the utmoft. As this latter cafe is a very improbable one, we fhall confine our obfervations principally to the former.

When a greater quantity of money flows in very rapidly, the induftry of the nation cannot keep pace with it; prices are fuddenly raifed very high; and though the fame effect follows in fome degree, even in this cafe, which we have feen to be the natural confequence of a greater quantity of money, a greater demand, and a rife in the price of commodities, *viz.* that a greater fupply is produced by the ftimulus given to induftry; yet, induftry muft have fome time in which to exert itfelf, and it alfo has its limits. Befides, it by no means follows, that the increafed demand for any commodity, is in the exact proportion of the increafed quantity of money brought into market for the purchafe of that commodity; fo that if the increafed fupply of it be regulated by the increafed quantity of money, independently of any regard to what is the actual amount of the increafed demand, the confequence will be that a larger quantity of the commodity will be brought into the market, than can find vent there, at leaft at a fair price. Now this circumftance is moft likely to happen, where a greater abundance of money flows in very rapidly; the immediate confequence is that there is a ftrong competition, and the price of the commodity is forced up much higher than would have been the cafe, if the flow of money into the market had been gradual and progreffive.

The fame evil refults from the circumftance of a greater abundance of money flowing in irregularly; partly in the mode juft detailed, and partly in another manner. Nothing renders the production of any commodity fo certain and fteady, and confequently nothing benefits a nation at large, and thofe whofe labour gives birth to it, fo much as a regular and known demand for it: but if at one time there is a large fupply of money in the market, and at another time the fupply is comparatively fmall, the manufacturer does not know how to regulate his labour, and as it is fafer and more prudent to err on the fide of a deficient fupply, the market is moft likely to fuffer in this refpect.

We may therefore conclude that where a greater abundance of money flows into a nation flowly, gradually, and regularly, the nation will be benefited by it: induftry and fkill will proceed in their natural courfe, by advances likewife flow, gradual, and regular; and the ground which they thus fecure, they will keep certainly and firmly. The wealth of the nation refting on a firm foundation, will not be apt to be fhaken or diminifhed. But, on the other hand, where the influx of wealth is fudden, rapid, or irregular, it will certainly tend much more to raife the prices than to increafe the fupply of commodities; and even that increafed fupply, as far as it does take place, will not be conftant or regular.

The other cafe, in which a greater abundance of money was ftated to be prejudicial to a nation, was that, where, previoufly to this additional fupply, the nation had exerted its induftry and fkill to the utmoft. This, it was added, was a very improbable cafe; yet it certainly exifted in Holland fome time before the French revolution deftroyed the commerce of that country. Money was there fo abundant, that it could fcarcely be employed in any manner, fo as to produce a fmall profit. In this country, therefore, under thefe circumftances, it is evident that a greater abundance muft have been prejudicial; the only effect it could have would have been that of ftill farther depreffing the profits of thofe who either had money to lend, or who employed it themfelves.

Let us now look at the effects on the property of a nation, which would be produced by diminifhing the quantity of its money; and, in order that we may perceive and trace thefe effects more clearly, let us fuppofe a particular cafe. Let us fuppofe that the quantity of money brought into the market for the purchafe of meat was diminifhed: the immediate refult would be, that each butcher, anxious to difpofe of his meat, would offer it below the ufual price; or, if we can fuppofe that they all perfifted in feeking, and actually obtained the ufual price, then, in this cafe, part of the meat muft remain unfold. In either cafe, the butchers would carry home lefs money than ufual, and of courfe would be able to fpend lefs on the commodities they were in the habit of buying; the venders of thofe commodities, in their turn, would either be obliged to difpofe of them all at reduced prices, or there would remain unfold a part of them. This would happen if the money withdrawn were what was ufually laid out in articles of confumption; but if it were what were ufually laid out on labour, and for the manufacture of commodities, it is plain that the price of labour would fall, and the fupply of manufactured articles would be diminifhed. In procefs of time, no doubt all things would accommodate themfelves to this diminifhed fupply of money; but in the mean while induftry would be checked, and the real ftrength and profperity of the nation would be affected.

It is a curious and difficult queftion to folve, whether, under any circumftances of the diminution of money, the fupply of commodities would ftill remain the fame, fo that, in fact, the only confequence would be that all things would be cheaper; in the fame manner, that the only confequence of an increafed fupply of money may, under certain circumftances be, that the price of commodities is raifed; or whether, as on the latter fuppofition, the confequence may be, either that the price is raifed, or that induftry being ftimulated, the fupply of commodities is increafed in a proportion equal to the increafe of money; fo, on the former fuppofition, of a diminution of money, the confequences may be either a diminution of price, or a proportional diminution of fupply. One thing, however, is certain, that as it is fcarcely poffible for money to flow into a nation in greater abundance than formerly, without ftimulating the induftry of the nation, whatever may be its permanent effects on the price of commodities; fo it is fcarcely poffible for money to be taken away from a nation, without checking its induftry, whatever may be the effects of this meafure on price.

Dr. Smith juftly obferves, that it is impoffible to determine what is the proportion which the circulating money of any country bears to the whole value of the annual produce circulated by means of it; but though it is impoffible to determine this, yet one rule for approximating towards the truth is laid down, which, as it feems to proceed on an erroneous idea of the nature of money, deferves fome notice in a difcuffion on the principles of that commodity. It has been faid, that the quantity of money required to conduct the commerce of any nation, muft be directly as the amount of that commerce, and as the rapidity with which the money circulates; it is this latter divifion of the rule for eftimating the neceffary quantity of money, that requires fome notice, as proceeding on an erroneous idea of it. Whenever any commodity employed as money ceafes to circulate, it ceafes to be money; it is only money, ftrictly and properly fpeaking, while it circulates; and in the intervals of its circulation,

culation, be they long or short, it suffers a temporary loss of that character, because it is not then performing the office of money. A thousand guineas locked up in the chest of a miser, or by any other means kept unemployed, can with no more propriety be called money than a thousand ounces of plate, or a thousand medals of gold in the same situation. The phrase rapidity of circulation, therefore, ought to be set aside, as conveying an erroneous idea. To put this in a stronger and clearer point of view; let us suppose that the circulating medium of any country consists of a million guineas; and that there are coined at the mint an additional hundred thousand: while these continue in the mint, it could not with any propriety be said, that the circulating medium was increased one-tenth; nor could this be said, if, as soon as they were issued from the mint, they were locked up, and not brought into circulation. Let us now suppose, that the circulating medium consists of 1,100,000*l*., but that one-eleventh of this, or 100,000*l*., are constantly unemployed: they, strictly speaking, could not be said to constitute any part of the money of the nation; nor, if they were thrown into regular and constant circulation, could it be said that the rapidity of the circulation was increased, any more than it could be said with propriety that the circulation was increased by the additional supply of one hundred thousand guineas from the mint, or from the chest in which they had been locked up. It makes no real difference in the circulating medium of a country, whether the same hundred thousand guineas are constantly locked up, or when a sum to that amount, the guineas constituting it continually changing, is constantly unemployed: the circulating medium in both cases would be actually increased, if that sum were added to the money of the country; *i. e.* if it were brought into constant use; in neither case could it properly be said that the rapidity of circulation was increased.

An erroneous idea, founded on a similar misconception of the real nature of money, is very generally entertained respecting the cause of a high or low rate of interest. That the rate of interest should be low when money is plentiful in a country; and that, on the other hand, it should be high when money is scarce, are supposed to be the natural, obvious, and necessary consequences of these circumstances respectively. Now, as in the case of coin unemployed, it has not the character, and cannot fulfil the offices of money; so in the case of money not brought into competition with any given commodity, it cannot affect the price of that commodity. There is as little reason to suppose that an increased quantity of money would directly and necessarily raise the price of meat, if it were all expended in the purchase of bread, as to imagine that this increased supply, merely because it flows into a nation, should lower the rate of interest: the rate of interest, like the price of all commodities, must depend on the proportion between the supply and demand: if the increased quantity of money is employed to enlarge the supply of money to be lent out at interest, while the demand continues the same, then the rate of interest will be lowered; but if it is employed for any other purpose, then it can have no effect on the rate of interest. Such are the leading and most important topics connected with the discussion of the *principles* of money, to which alone this article has been confined. An attempt has been made to illustrate these principles, in the first place, by pointing out the real nature of money, or the qualities necessary in any commodity which is to be employed for the purpose of facilitating the interchange of what men possess for what they desire; in the second place, by pointing out the modes in which money operates in the interchange of commodities; and in the third place, by detailing and explaining the effects produced on the prosperity of a nation, by an increase or diminution in the supply of money. Some collateral and incidental topics have also been touched upon, all tending to the same object, *viz.* that of illustrating the nature of money, and the mode of its operations.

It has been thought proper to abstain from introducing any discussion respecting the different kinds of money that have been, or are, generally employed, or respecting the questions to which this branch of the subject would naturally give rise; as whether, if metallic money is employed, one metal alone should be the standard and legal tender, and the others should be permitted to circulate along with it, according to their market price; or whether the proportions should be fixed by law: the discussion of this point will fall under the head of SILVER. What are the advantages and disadvantages of a metallic and paper currency; and the various important questions connected with this branch of the subject of money; these will fall under the head PAPER *Currency*: and what circumstances affect the proportional value of the currency of one country, as compared with that of other countries; these will be considered under the head PAR *of Exchange*. In the course of the present article, the nature of value has been slightly touched upon; this will be more fully and particularly treated of under its proper head; and some further illustration of the nature and operations of money, will occur under the articles PRICE, STOCK or *Capital*, and WEALTH, which could not so properly find a place in this article.

In noticing the authors that treat on the *principles* of money, it is scarcely necessary to mention Smith, in his Wealth of Nations; on this, as on most of the fundamental topics of political economy, this author is perspicuous and satisfactory, though he does not always exhaust the subject on which he treats.

On the *principles* of money, much perhaps may be gained from his incidental illustrations, and from the general principle that pervades his works, and lies at the foundation of his system, than from what he directly advances on the subject. Hume, in his essay "Of Money," has thrown out only some very luminous ideas, which, though not always exactly correct, as we have endeavoured to prove, yet almost unavoidably, in the mind of an attentive reader, give rise, not merely to the perception of the error which they contain, but also to such a train of reflections as still further illustrate the subject. Indeed it is the singular merit of this author in his essays, that he guides and stimulates his readers to reflection. Sir James Stewart, in his Enquiry into the Principles of Political Economy, has entered pretty fully into the subject of money in the 28th chapter of his 2d book: there is a very striking and essential difference between the works of this author and that of Smith in his Wealth of Nations. Throughout the whole work of Stewart, there is that want of methodical and luminous arrangement, that obscurity and unsatisfactoriness in reasoning, and that clashing and contradictoriness of opinion, which must exist, where there are no clear and well grounded general principles established and pursued. His chapter on money, however, contains many valuable and sound doctrines; pushed in some instances too far, as where he endeavours to prove that an increase of money in a nation cannot affect the prices; the opinion that it necessarily, uniformly, and permanently must raise the prices, is no doubt erroneous; but if the illustrations in this article are correct, the contrary opinion, that it cannot produce this effect, is also erroneous. The controversy which took place towards the close of the 17th century respecting the state of the currency, and that which took place a few years ago, gave rise to many pamphlets, some of which treat directly and entirely on on the principles of money, and others of them only incidentally; these are, of course, of various merit, and will not add much that is satisfactory and solid to what may be gathered from Smith, Hume, and Stewart.

Money, *False*, or *Base*, is either struck by an unqualified person, and of unstatutable metals; or that which has lost of its weight, either by being clipped on the corners, or filed on the edges: or, lastly, by having some of its surface eaten off; if gold, by aqua regia: if silver, by aqua fortis.

Another kind of base money is that made of pieces of iron, copper, or other metal, covered on each side with a thin plate or leaf of gold or silver, neatly soldered and joined round the edges, and struck, like other coin, with figures, legends, &c. only to be distinguished from them by the bulk and weight, and sound.

Money-*Bills*, in *Parliamentary Language*, comprehend all bills, by which money is directed to be raised upon the subject, for any purpose or in any shape whatsoever; either for the exigencies of government, and collected from the kingdom in general, as the land-tax: or for private benefit, and collected in any particular district, as by turnpikes, parish-rates, and the like. With respect to these bills, the commons are so reasonably jealous of their privilege of framing new taxes for the subject, that they will not suffer the other house to exert any other power but that of rejecting: they will not permit the least alteration or amendment to be made by the lords to the mode of taxing the people by bills of this nature.

Money, *Cert*. See Cert-money.

Money, *Chimney*, *Madning*, *Poll*, *Prest*, *Prestation*, *Salvage*, *Ship*, and *Trophy*. See the several articles.

Money-*wort*, in *Botany*. See Nummularia.

MONEYERS, Moneyors, or *Moniers*, officers of the mint, who work and coin gold and silver money; and answer all the waste and charges.

Moneyers is sometimes also used for hawkers; or those who make a trade of turning and returning money.

MONEYGALL, in *Geography*, a small post-town of Ireland, in the King's county. It is 69 miles S.W. from Dublin, and 10 S.W. from Roscrea.

MONEYMORE, a small post-town of the county of Londonderry, province of Ulster, Ireland, in the southern part of the county. It is 83 miles N. from Dublin, and two miles from Cookstown.

MONFALCO, a town of Spain, in Catalonia; 5 miles N.E. of Cervera.

MONFALCONE, a town of Italy, capital of a small principality of the same name, seated on the coast of the Adriatic, and containing about 1200 inhabitants; the whole territory comprehends 20 villages, and about 4600 inhabitants; 15 miles N.W. of Trieste. N. lat. 45° 53′. E. long. 13° 30′.

MONFALOUT, or Momflot. See Manfalout.

MONFIA, an island in the Indian sea, near the coast of Africa, governed by a king, tributary to the Portuguese; about 60 miles in circumference. S. lat. 7° 30′.

MONFORT-l'amaury, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Versailles. The place contains 2400, and the canton 15,809 inhabitants, on a territory of 212½ kiliometres, in 28 communes.

MONFORTE, or Montfort, a town of Portugal, in the province of Tras-los-Montes; 33 miles W. of Braganza.—Also, a town of Spain, in Valencia; 13 miles W.N.W. of Alicant.—Also, a town of Portugal, in the province of Alantejo; 12 miles S. of Portalegre. N. lat. 38° 56′. W. long. 7° 12′.—Also, a town of Portugal, in Beira; 15 miles S.E. of Castel Branco. N. lat. 39° 38′. W. long. 6° 58′.—Also, a town of Sicily, in the valley of Demona; 10 miles W.S.W. of Messina.

Monforte *de Lamos*, a town of Spain, in Galicia; 15 miles N.N.E. of Orense.

MONGAELLI, a sea-port of Madagascar, on the W. coast. S. lat. 13° 55′.

MONGAGUBA, a river of Brazil, which runs into the Atlantic, S. lat. 9° 20′. W. long. 34° 56′.

MONGALLO, or Gallo, a kingdom of Africa, N. of Mocaranga; having a capital of the same name, on a river called Mongallo, which runs into the Indian ocean, S. lat. 10° 5′. E. long. 39° 14′.

MONGALORE, a town of Hindoostan, in the Carnatic; 15 miles W. of Gingee.

MONGAN, a town of Chinese Tartary. N. lat. 41° 46′. E. long. 123° 54′.

MONGANORE, a town of Hindoostan, in Golconda; 12 miles W.N.W. of Rachore.

MONGAS, a country of Africa, S. of Sofala, furnishing a great quantity of gold, particularly at Massapa and Maninas, and the mountain of Ophir, whence, as some have supposed, Solomon derived his treasures. The Portuguese are settled at Massapa, under the government of Mozambique.

MONGASABA, a town of Hindoostan, in Oude; 28 miles N. of Kairabad.

MONGAULT, Nicholas-Hubert de, in *Biography*, a man of letters, who was born at Paris in 1674, entered, at an early age, into the congregation of the Fathers of the Oratory, and was sent to study philosophy at Mans. The system then taught in the schools was that of Aristotle, which, as Mongault could not comprehend, he did not scruple to reject, and adopted that of Descartes in its stead, the principles of which he openly maintained in public exhibitions. His want of health obliged him to retire, in 1699, to the college of Burgundy, at Paris, where he finished a translation of Herodian, which was published in the following year. In a few months afterwards, he published the first volume of a translation of the "Letters of Cicero to Atticus," and almost immediately after, Colbert, archbishop of Toulouse, gave him apartments in his palace. In a short time the superintendant Foucault, who wished for the conversation and services of a man of learning, prevailed upon Mongault to reside with him, and obtained for him admission into the Academy of Inscriptions and Belles Lettres. In 1710, the duke of Orleans appointed him tutor to his son, the duke of Chartres: in this situation he is celebrated by Duclos, in his Memoirs of the Regency, as "a man of parts and erudition; a theologian, who thought freely on the subjects of religion;" but whether he thought his pupil incapable of enlightened principles, or that princes should themselves be subjected to the most powerful restraints, he certainly endeavoured to impress on the mind of the young prince a system of religion which had a tendency to excite the greatest degree of terror. The result was, as might have been expected, that after his father's death, the youth went into all the austerities of monkish devotion, in which he continued till his death. The abbé's services were, however, so well received by the family, that he obtained, through their means, several church benefices and civil places. For many years of his life he was subject to melancholy, but when free from this complaint, his conversation was lively and instructive. He died in 1746: besides his translation of Cicero's letters, in six volumes, he published two dissertations in the Memoirs of the Academy of Inscriptions. He was admitted into the French academy in 1718. Moreri.

MONGELLA, in *Geography*, a small island in the Persian gulf, near Cape Bardistan. N. lat. 27° 37'.

MONGER, a little sea vessel which fishermen use.

When a word ends with *monger*, it signifies *merchant*; from the Saxon *manger*, i. e. *mercator*.

MONGERAH, in *Geography*, a town of Hindoostan, in Oude; 55 miles N.W. of Manickpour.

MONGHIR, a town and fortress of Hindoostan, in Bahar, on the S. coast of the Ganges; 40 miles E. of Bahar. N. lat. 25° 25'. E. long. 86° 36'.

MONG-HOA, a city of China, of the first rank, in the province of Yun-nan, to which no district belongs; it is surrounded with high mountains, which abound with the animals that yield musk. N. lat. 25° 18'. E. long. 100° 4'.

MONGIA, or MUGIA, a sea-port town of Spain, in Galicia, near the sea-coast; 35 miles W.N.W. of Compostella.

MONGIARDIA, a town of the Ligurian republic; 23 miles N. of Genoa.

MONGLEE, a town of Hindoostan, in Dowlatabad; 28 miles S. of Renapour.

MONGLEGOARRY, a town of Hindoostan, in the circar of Guntoor; 12 miles E. of Guntoor.

MONGLETORE, a town of Hindoostan, in Golconda; 30 miles S.W. of Rachore.

MONGOL, one of the small Philippine islands, N.E. of Masbate. N. lat. 12° 14'. E. long. 123° 55'.

MONGOLBONG, one of the smaller Philippine islands, E. of Masbate. N. lat. 12° 10'. E long. 124°.

MONGOLES, MONGULS, or *Moguls*, a people of ancient origin, and of widely extended dominions in the north-western parts of Asia; whose conquests, as far as history can trace them, might be consigned to oblivion, if they had not produced in successive ages signal revolutions in the state of governments and of mankind. It is not easy to separate them from the people called Tartars, or to ascertain their first rise, and their early progress towards that vast empire which they ultimately acquired. Both the Moguls and Tartars are said to have been the descendants of Japhet, the eldest son of Noah. The progeny of Magog, Meshech, and Tubal, as many learned men have maintained, planted both the Scythias, and consequently the country of the ancient Moguls and Tartars. The Tartars claim priority of origin, and pretend to be descended from Turk, the eldest son of Japhet, whom they call Japhis. From their ancient ancestor they derive the name of Turks, which they seem to have retained till the time of Jenghiz Khan. This name was succeeded by that of Tartars or Tatars; and this appellation was afterwards changed by some of their tribes into that of Monguls or Moguls, which appellation prevailed till the dominion of the people, thus denominated, over the southern provinces of Asia expired, when the former name was again resumed. The immediate successor of Turk was his son Taunak, who contributed to enrich and aggrandize the nation over which he presided; and the government descended in this line, from which Timur Beg at a future period is said to have sprung. One of these princes, called Alanza Khan, having twin sons, *viz.* Tatar and Mogul, or more properly Mung'l, divided his dominions between them, not long before his decease. From Tatar Khan, the Tatars or Tartars derived their name, as the Moguls deduce theirs from Mogul or Mung'l Khan. The latter prince, the first monarch of the Moguls, was of a very melancholy disposition, which circumstance gave occasion to his name; *Mung*, in the Tartarian language, signifying *melancholy*. At his death he left four sons, from the eldest of whom, in a direct line, descended the famous Jenghiz Khan. Kara Khan, the eldest of these sons, ascended the throne upon the decease of his father; and the Tartars say, that in his time the true religion was banished out of the world, and idolatry substituted in its place. His son and successor, Ogus Khan, is said to have worshipped the true God; and issued an order, that every one in his dominions should embrace the true religion. Ogus Khan was a valiant and victorious prince, and subdued by his arms the people of Kitay or Kathay, and those of other nations. Ogus Khan, who extended his conquests through a long reign, as the Tartars say, of 116 years, was held in high veneration over a great part of the East, and regarded as the greatest hero, except Jenghiz Khan, that ever lived in the eastern parts of the world, by the Turks and Tartars of all denominations. The Ottomans, or Ottoman Turks, so called in contradistinction to the Turkish or Tartarian tribes settled in Great and Little Tartary, from him assume the name of Oguzians; and pretend that the Othman or Ottoman family is descended in a direct line from Ogus Khan. The Tartar historians blend many fictions with their account of the Tartarian and Mogul princes, so that at this distance of time, and without the assistance of collateral records, it is impossible to distinguish between the true and the fabulous relations which their history contains. Although they are mistaken in their chronology, as is the case particularly with Abu'l Ghazi Bahadur, whose Tartarian MS. containing the genealogical history of the Turks, Tartars, and Moguls, was brought into Europe by M. Von Strahlenberg, by him translated into the German tongue, and afterwards into French, and published at Leyden in 1726, who refer Ogus Khan to the ninth generation from Noah; it nevertheless appears, that this prince was at the head of a powerful nation in the East, from which the present Tartars sprung, and rendered himself famous by his conquests. Some have supposed, that this Ogus Khan was the same with the Madyes of Herodotus, and, therefore, that the conquests of this prince terminated in the reduction of the Upper Asia, and that he put an end to his expeditions about the year 631 B.C.

Dismissing the ancient history of the Mongoles or Moguls, between whom and the Tartars many contentions subsisted for several successive ages, we shall confine our account of them, in the sequel of this article, to a later period. In the 9th century these nations appeared roaming about the northern side of China and Corea; in the west, or Modern Mongolia, the Mong-u, afterwards called Monk-kos and Mongoles; further to the east, the Kitanes; and lastly, beyond Corea, as far as the eastern ocean, the Niudsches or Kin, who, generally speaking, are the same people with the Tunguses, and the Mandschu or Mantchew, the present sovereigns of China. These three people, gradually increasing, became at length powerful nations; though at first they were weak and inconsiderable. In the 10th century, the Kitanes first subdued the two other nations, and then the northern provinces of China. The Niudsches, however, soon rebelled, and being called to their assistance by the Chinese, gained the ascendancy over them, as well as the Kitanes. Upon this, a part of the latter retreated westwards, and took possession of the Lesser Bucharia, where they have since borne the name of Karakitans, or Karakitayans. In the mean time the Niudsches ruled over the north of China, and the Mongoley as far as the eastern ocean. The Mongoles were divided into several hordes, who, notwithstanding the supremacy of the Niudsches, had their own khans. It was one of these petty princes, Temudschin or Temulin, who, under the name of Tschinghis-khan, or Jenghiz-khan, became the founder of a new monarchy, and

and one of the moſt memorable ravagers of the world. He was only thirteen years old, on the death of his father in 1176, when he became ſovereign of 40,000 families. His career laſted twenty years; during which time he deſolated the countries and ſubjected the people from the Mongoley and from China to the further Aſia, and in Europe quite up to the ſhores of the Dnieper. In the firſt three years of his warfare, he ſubdued the Naimanes, Kirghiſes, and the other Tartarian hordes. He received the voluntary ſubmiſſion of the Igures, a poliſhed nation, who communicated the art of writing to the Mongoles, from whom afterwards the Mandſchu received it. About the ſame time he preſſed forward into the north-weſtern parts of China, and made the king of Tangut his vaſſal. Soon after he turned his arms againſt the Niudſches, proceeding in his conqueſts, murder, and rapine, as far as the capital of Irnking, forced it to ſurrender, and found in it the wiſe Ilidſchutzay, a truly great and noble-minded man, whom he made his firſt officer of ſtate; and who not only reſcued ſeveral millions of perſons from their impending fate, who would otherwiſe have fallen victims to the ſavage Mongoles, but who may be alſo juſtly ſaid to have created the Mongolian ſtate, by poliſhing the manners of that people, and, as far as he was able, diſſeminating among them the arts and ſciences. While the Mongolian army was fighting againſt the Niudſches, in 1217, the flames of war broke out with increaſing fury on the weſtern ſide of the Mongolian empire, which, in proceſs of time, communicated to all the countries round, and the Mongoles advanced to nether Aſia, and thence again to Europe. Having defeated Keſchluk, king of the Naimanes, and cauſed the country to ſubmit, Tſchinghis haſtened to meet the ſultan of Khovareſm, who had cauſed his ambaſſador to be ſlain, and who was his mightieſt and moſt dangerous adverſary, and obliged him to ſubmit. In 1220, Khovareſm, the capital, was captured, and on this occaſion the number of the killed amounted to upwards of 100,000 perſons, and every Mongolian warrior received to his own ſhare twenty-four ſlaves. About the ſame time all the countries and nations round, as far as the Oxus, ſubmitted to his arms. Tſchinghis now diſpatched an army acroſs that river, took Khoraſan, and drove the new khovareſmian ſultan to India. Another army was engaged in China againſt the Niudſches; a third was making conqueſts in Kaptſchak, on the N. ſide of the Caſpian; and a fourth, which had reduced the countries on the S. ſide of that ſea, was now advancing againſt the Kaptſchaks. In 1223, the Polovtzes, a branch of the Kaptſchaks, and Ruſſians loſt the great battle on the Kalka, and were purſued as far as the Dnieper by the Mongoles; who, without proceeding farther into Ruſſia, returned, laden with their booty, by Kaptſchak to Bucharia, to join Tſchinghis. In this year Tſchinghis convoked a general diet, in which was ſettled the form of government to be adopted by the conquering countries. His intended progreſs to India was reſiſted by the army; and, therefore, after an abſence of ſeven years he returned, in 1225, to Mongoley; but in the following year he was obliged to undertake a campaign againſt the rebellious Tangut. The Mongoles penetrated acroſs the great ſandy deſert into that country, and were every where victorious; the royal race was exterminated, and the inhabitants were ſlaughtered in ſuch ſhocking multitudes, that ſcarcely one in fifty was ſpared. After this conqueſt, and when Tſchinghis was meditating the deſtruction of the empire of the Niudſches in China, death, in 1227, terminated all his projects. Oktay, the ſon and ſucceſſor of Tſchinghis, put an end to the empire of the Niudſches in China, and reduced the whole northern China to his authority: he then made war upon the kings of Corea, and determined, with an army of more than a million and a half of men, to overrun the world from one end of one hemiſphere to the other. With 600,000 of his troops he marched in perſon againſt the dynaſty of Song in ſouthern China; while the main body of his army, under the command of his ſon Kayuk and his nephews Baaty and Menku, proceeded to the weſt. In their progreſs they ſubdued the Tcherkaſſes and Avkhaſes, penetrated the Baſchkirey, into Kazan and Bulgaria, and finally came to Moſcow. Fourteen Ruſſian towns were burnt in one month, February 1238. Baaty proceeded toward Novgorod, and ordered all the inhabitants in his paſſage to be maſſacred: but ſuddenly changing the direction of his march, he haſtened to the regions of the Polovtzes and Bulgarians on the Volga. After a deſperate reſiſtance of ten weeks, Kief ſurrendered (1240), and received a Mongolian viceroy. All Ruſſia, except Novgorod, was now tributary to the Mongoles, who every where appointed viceroys, without expelling the Ruſſian princes. Baaty khan, with two great armies, ravaged Poland, Sileſia, and Moravia; marched in perſon into Hungary, pillaged and murdered wherever he went, both here and in Slavonia, Boſnia, Servia, and Bulgaria. While the Mongoles were committing ſuch horrors in Europe, and proſecuting the war againſt the Coreans and the ſouthern Chineſe, they overran likewiſe, with their numerous hoſts, the hither Aſia. A force was ſent through Tſcherkaſſia, or Circaſſia, to make an incurſion upon Armenia; and the Mongoles penetrated into the regions of Arbela, marched through Nineveh, approached Bagdad, conquered Erzerum, ravaged and ſubjugated ſeveral cities and diſtricts of the Leſſer Aſia, and in 1242 made the ſultan of Iconium their vaſſal. In the following year they purſued their inroads into Syria, and came to Aleppo. The death of Oktay ſaved Aſia for a time, and Europe for ever. After an interregnum of four years, the ſucceeding grand khan Kayuk made formidable preparations for war in Europe, but death defeated his projects. His ſucceſſor Menku aboliſhed the caliphate, and ſubjected the ſultan of Iconium and Aſia Minor, as far as the ſtraits of Conſtantinople, to the Mongolian authority. Menku was ſucceeded in 1259 by Koblay. The diſtance of the paramount ſovereign from the other Mongolian ſtates, which extended from the eaſtern ocean as far as the Dnieper and the Mediterranean ſea, accelerated by diſcord and ambition the diſſolution of this enormous monarchy, which now ſeparated into the following extenſive ſtates, *viz.* China, Iran or Perſia, as far as the hither Aſia, Dſchagatay or Tchagatay, ſo called after its founder, Kaptſchak, and Turan; which ſee reſpectively. The next ambitious conqueror, or cruel deſtroyer, as we may call him, that occurs to our notice in the hiſtory of the Mongoles, is Timur or Tamerlane, who was prince of Keſch, near Samarcand, about the time when the Mongoles were entirely expelled from China. His dominion took its riſe in Grand Bucharia, a part of the ancient Dſchagatay. Having ſucceeded in the reduction of that empire, he received, in 1369, the homage of the grandees, and the title of the ſovereign of the world. Of his expeditions and conqueſts we have given ſome account under the article MOGUL *Empire*, and referring to his biographical article, we ſhall here only ſay that juſt as he was preparing to reſtore the dominion of the Mongoles in China, he was removed by death. His ſucceſſors loſt, one after another, all the countries which Tamerlane had left them, Bukharay and Khoraſan excepted; and even theſe the laſt khan Baber, in 1498, was obliged to abandon, who, however, from being an outcaſt and a fugitive, became the founder of the ſtate of Grand Mongolia,

Mongolia in Hindooſtan. With the fall of the Grand Mongolian empire of the Tſchinghiſes began alſo the epocha of their decline: the diſſolution into ſmaller ſtates, which parted again into ſmaller ſtill, and were then reduced to ſubjection, at length brought about a diviſion into ſtems and hordes, and, conſequently, a complete retrogradation from the ſtate of civilization to the condition of raw uncultivated man. It appears that many centuries ago the Mongoles were divided into two leading nations, whoſe partition might probably be owing either to national circumſtances, or to a natural ſeparation by mountains, and afterwards kept up by the ſeparate intereſts of their princes, or from a national enmity occaſioned by perpetual diſſentions. Theſe two nations were brought to a union into one common ſtate by the great Tſchinghis; but on the deſtruction of the monarchy which he had erected, they were ſeparated again by the ancient feuds, and have ever ſince, to their mutual ruin, been engaged in almoſt perpetual hoſtilities. The Mongoles, properly ſo called, compoſe the one, and the Doerbœn-Oiræt the other of theſe nations. Doerbœn-Oiræt means the quadruple alliance, and is the common appellation of four principal races, *viz.* the Oeloet, Kho-it, Tummut, and Barga-Burat. The Oeloet conſtitute that branch, which in Weſtern Aſia and in Europe is known under the name of *Kalmucks*, which ſee: the ſecond ſhoot, Kho-it, is almoſt extinct, if we except ſome remains among the Soongares and Mongoles: of the Tummut, even the place of their preſent abode is not certainly known; and the fourth ſtem, Barga-Burat, which probably, at the time of the troubles excited by Tſchinghis, took up its reſidence in the mountains about the Baikal, has, with all its branches, ever ſince the conqueſt of Siberia, been under the Ruſſian ſovereignty. The Mongoles comprehend the remainder of that people who were driven out of China in the 14th century by the dynaſty of Ming, and are at preſent for the moſt part under the Mandſhur ſovereigns of that empire; though a ſmall portion of them own the Ruſſian ſceptre. Since the demolition of the Soongarian authority, and the reſtoration of peace in the Mongoley, they have inhabited the ſpacious region between Siberia and proper China, from the eaſtern ocean to the Soongarey; and at preſent there is ſcarcely any diſcernible difference between the yellow Mongoles, living from remote ages under the Chineſe protection, and the former Tſchinghiſes or Kalkas-Mongoles. See KALKAS.

When Siberia was conquered by the Ruſſians at the beginning of the 17th century, the Mongoles were ſtill a numerous and free people, governed by their own khans, under whoſe ſovereignty were alſo ſeveral Siberian nations. At firſt they ſubmitted to the Ruſſian arms; ſoon afterwards they regained their liberty, and even granted ſupport to ſeveral nations of Siberia in their reſiſtance to that power. In their inteſtine wars with the Kalmucks, they were generally conquerors, with the loſs, however, of one race after the other. Their frequent and bloody wars with China were ſtill more unfortunate in their iſſue, as their perpetual feuds finally terminated in a complete ſubjugation. At preſent they are not in a condition to liberate themſelves from the yoke; though they have preſerved their paternal ſeat, and oſtenſibly live under the government of their own hereditary princes. The Mongoles, who now form a part of the inhabitants of the Ruſſian empire, withdrew themſelves in the 17th century from the Chineſe dominions, and put themſelves under the Ruſſian ſupremacy; but this ſeceſſion was reſtrained by a border treaty entered into in the 18th century between Ruſſia and China, the former ſtipulating not to give admittance any more to Mongolian runaways. The Ruſſian Mongoles inhabit the regions about the Selenga in the Irkutſkoi diſtrict of the government of Irkutſk, their dwelling place extending from the 122d to the 125th degree of longitude, and between the 50th and 53d degree of north latitude. They conſiſt of ſeven ſtems, and theſe of 20 families or "aimaks," which, by the enumeration of the year 1766, compriſed, beſides 219 baptized, 6918 males.

The vaſt country of the Mongoles or Moguls is bounded on the N. by Siberia, on the E. by Eaſtern Chineſe Tartary, on the S. by the great wall and Leao-tong, and on the W. by Independent Tartary. It was partly from theſe dry deſerts that thoſe conquerors iſſued, who made all Aſia tremble. The Mogul nation is ſub-divided into a multitude of others, who all ſpeak the ſame language, called the Mogul language, comprehending ſeveral dialects underſtood by one another. Theſe have neither towns, villages, nor houſes; they form themſelves into wandering hordes, and live under plain tents, which they tranſport from one place to another, according to the temperature of the different ſeaſons, or the wants of their flocks; they paſs the ſummer on the banks of rivers, and the winter at the foot of ſome mountain, or little hill, which ſhelters them from the ſharp north wind. Each of theſe tribes has its reſpective limits, nor can they go beyond them without being thought to commit an act of hoſtility. They are naturally clowniſh, and dirty in their dreſs, as well as in their tents, where they live amidſt the dung of their flocks, which, when dried, they burn as fuel. Enemies to labour, they ſatisfy themſelves with the food ſupplied by their flocks rather than take the trouble of cultivating the earth; they neglect agriculture more from pride, alleging that "the graſs was for beaſts, and beaſts for man." The men hunt the numerous beaſts, and game, that roam through their vaſt wilds; the women tan leather, dig the culinary roots, prepare the winter proviſions dried or ſalted, and diſtil the koumiſs, or ſpirit of mares' milk. In ſummer they live only on milk, uſing, without diſtinction, that of the cow, mare, ewe, goat, and camel. Their ordinary drink is an infuſion of coarſe tea in warm water; with which they mix cream, milk, or butter, according to their circumſtances. Before they diſtil their ſour milk, thoſe of better condition mix with it ſome of the fleſh of their ſheep, which, as well as the milk, has been left to ferment. This liquor is ſtrong and nouriſhing; and their moſt voluptuous orgies conſiſt in getting drunk with it. Mead and brandy are now great favourites with them. The Moguls are rather ſhort in ſtature, with flat viſage, ſmall oblique eyes, thick lips, and a ſhort chin, with a ſcanty beard. Their ears are large and prominent, the hair black, and the complexion of a reddiſh or yellowiſh-brown; but that of the women is clear, and of a healthy white and red. They have ſurpriſing quickneſs of ſight, and apprehenſion. In their diſpoſition they are free, open, and ſincere; they are docile, hoſpitable, beneficent, active, and voluptuous. Induſtry is a virtue, entirely female; and though great, it is accompanied with perpetual cheerfulneſs. They pride themſelves chiefly on their dexterity in handling the bow and arrow, mounting on horſeback, and hunting wild beaſts. Polygamy is allowed, though they commonly content themſelves with one wife; marriages are celebrated at an early age, and the bride brings a dower in cattle or ſheep. Their tents are circular, in form of the fruſtum of a cone, and covered with a large piece of white or grey felt. A round hole in the top gives paſſage to the ſmoke, which riſes from a fire made in the middle of the tent. Theſe tents, which they have been accuſtomed to prefer to the Chineſe houſes, are cold in winter, and inſupportably warm, and noxiouſly damp, in ſummer.

The tents of the nobles are hung with ſilk, and the floor covered with Perſian carpets. The houſhold utenſils are numerous; and in the ſuperior tents are veſſels of pewter, ſilver, and porcelain. Their dreſs conſiſts of a flat yellow bonnet, which covers the head that is ſhaven, except one lock, wide trowſers, a veſt of light ſtuff with narrow ſleeves, and a girdle, which ſupports the ſabre, knife, and implements for ſmoking tobacco. The outer veſtment is of cloth, or ſkin, with wide ſleeves, and linen is wound about the feet, over which are drawn buſkins of leather, generally black or yellow. Shirts are unknown. The dreſs of the women is the ſame, but inſtead of the outer garment they wear a gown without ſleeves. The ſkins, which they uſe for clothing, are generally thoſe of ſheep; the wool ſide being inmoſt, and the ſkin on the outſide. They are well acquainted with the method of preparing and whitening theſe ſkins. But theſe ſkins, however carefully prepared, exhale a ſtrong and diſagreeable ſmell, on which account they are called by the Chineſe "Tſao-tatſe," ſtinking Tartars. The hair of the females is long, and plaited in treſſes.

When paſturage begins to fail, all the tribes ſtrike their tents, generally from ten to fifteen times in the year, proceeding in the ſummer to the northern, and in the winter to the ſouthern wilds. The herds, men, women, and children, form a regular proceſſion; and are followed by the girls, ſinging with harmony and ſpirit. The amuſements of theſe jovial wanderers conſiſt in running races on horſeback, in which even the girls excel; archery, wreſtling, pantomime, dances, and the ſongs of the young women, generally accompanied by the lute, viol, and pipe; the themes of their ditties being tales of gigantic chivalry, and amorous adventures and ſentiments; but the melody is harſh and diſmal. Cards are not unknown, but the favourite game is cheſs. The bodies of the princes and chief men are burned with many ſolemnities; and the tombs are ſometimes walled, and ornamented with high poles and fantaſtic drapery. They are unacquainted with the uſe of money, and trade only by barter. Such, alſo, with ſome ſhades of difference, are the manners of the Tartars and Mandſhurs. In the Mogul language there are many books written in the various countries to which their wide conqueſts extended.

The religion of the Mogul Tartars is confined to the worſhip of Fo. For their "Lamas" they entertain the moſt ſuperſtitious veneration; though theſe are clowniſh, ignorant, and licentious prieſts, yet to them they attribute the power of calling down hail or rain; and to them they give the moſt valuable of their effects in return for prayers, which they go about reciting from tent to tent. Theſe people are very devout, and continually wear hanging at their necks a kind of chaplet, over which they ſay their prayers.

All the Moguls are governed by khans, or particular princes independent one of the other, but all ſubject to the emperor of China, whom they conſider as the grand khan of the Tartars. When the Mantchews ſubdued China, they conferred on the moſt powerful of the Mogul princes the titles of "vang," "peilé," "peizé," and "cong," which correſpond to our titles of king, duke, count, and marquiſs; each of them had a revenue aſſigned him, but far inferior to the appointments of the Mantchew lords at Pe-king. The emperor ſettled the limits of their reſpective territories, and appointed the laws, according to which they are at preſent governed. Theſe tributary khans have not the power of condemning their ſubjects to death, nor of depriving them of their poſſeſſions: the two caſes of death and confiſcation being reſerved for the ſupreme tribunal eſtabliſhed at Pe-king for the affairs of the Moguls, to which every individual may appeal from the ſentence of his prince, who is obliged to appear in perſon whenever he is cited.

All the Mogul nations, under the Chineſe government, of which we have given an account in the cloſing paragraph of this article, are divided into four principal tribes, which are the Moguls, properly ſo called, the Kalkas, Ortous, and Tartars of Kokonor. The country of the Moguls, according to the map of Chineſe Tartary, taken from the Memoirs of the Jeſuits, extends more than 300 leagues from E. to W., and 200 from N. to S.; it is incloſed between the country of the Ortous, the great wall, Eaſtern Tartary, and the country of the Kalkas; theſe people compoſe 49 "ki," or ſtandards; every ſtandard comprehending an indeterminate number of companies, each of which conſiſts of 150 heads of families; and each company may be reckoned to contain 1000 individuals. Beſides theſe 49 ſtandards, there are five others, under the immediate government of the emperor of China, and commanded by officers whom he ſends thither.

The beſt cultivated canton of all the Mogul territories is the diſtrict of "Cartching," near the great wall, where the emperor every year hunts, and where he has cauſed to be built ſeveral pleaſure-houſes, the principal of which is "Geho." The extenſive domains in this diſtrict, belonging to the emperor, are let out to farmers, and the number of cattle kept by them is immenſe. It has been ſaid that they reckoned there 190,000 ſheep, diſtributed into 225 flocks, and almoſt as many oxen and cows, divided into herds, each of which contained 100. The number of ſtallions there is more conſiderable. Theſe riches in farms, ſtuds and flocks make greater impreſſion on the minds of the Tartar and Mogul princes, and render them much more ſenſible of the majeſty of the emperor, than all the magnificence of his court at Pe-king. Anc. Un. Hiſt. vol. xviii. Tooke's Ruſſia, vol. i. Groſier's China, vol. i. See MOGUL *Empire*, and TARTARY.

MONGON, a town of Peru, ſituated on its coaſt, in the South Pacific ocean; 10 leagues N. of the harbour of Guarmey, and four leagues from Bermajo iſland: it is known at ſea by a high mountain juſt over it, which is ſeen at a greater diſtance than any others on this part of the coaſt.

MONGON, *Cape*, lies on the S. ſide of the iſland of St. Domingo.

MONGOOSE, or MONGOOZ, in *Zoology*, is a ſpecies of *lemur* in the Linnæan ſyſtem, the woolly maucauco of Pennant, and by ſome called the Macaſſar fox. See LEMUR *Mongoz*.

MONGOPUNGOLE, in *Geography*, a town of Hindooſtan, in the circar of Meywar; 36 miles E. of Cheitore.

MONGOU KIAMEN, a poſt of Chineſe Tartary. N. lat. 44° 46'. E. long. 125° 28'.

MONGUILLEM, a town of France, in the department of the Gers; nine miles N.W. of Nogaro. N. lat. 43° 52'. W. long. 0° 7'.

MONGUIPATANE, a town of Hindooſtan, in the circar of Aurungabad; 24 miles S. of Aurungabad.

MONGULCOTE, a town of Hindooſtan, in Bengal; 18 miles N. of Burdwan.

MONGULHAUT, a town of Hindooſtan, in Bengal; 16 miles N. of Rungpour.

MONGUMMA, a town of Hindooſtan, in Boggilcund; 15 miles N.E. of Rewah.

MONHEGAN, or MENHEGAN, a ſmall iſland in the Atlantic

Atlantic ocean; 12 miles S.E. of Pemaquid Point, in the county of Lincoln and ſtate of Maine.

MONHEIM, a town of the duchy of Berg, on the Rhine; nine miles S.S.E. of Duſſeldorp.—Alſo, a town of Bavaria, in the principality of Neuburg; 18 miles W.N.W. of Neuburg. N. lat. 48° 47′. E. long. 10° 46′.

MONI, a ſmall iſland in the gulf of Engia.

MONIAGUR, a town of Hindooſtan, in Concan; 48 miles N. of Bancout.

MONIAN, a town of Bengal; 20 miles S. of Calcutta.

MONIEH, one of the ſmaller Hebrides. N lat. 57° 28′. W. long. 7° 36′.

MONJES, a cluſter of ſmall iſlands in the Spaniſh main, near the coaſt of South America. N. lat. 12°. W. long. 70° 40′.

MONIGLIA, Gio. Andrea, of Florence, in *Biography*, member of the academy della Cruſca; a phyſician by profeſſion, was author of a great number of poems for muſic. He may be regarded, ſays M. Laborde, as one of the firſt who began to reform the abuſes of the age; but this was only in his dramatic works, they were all printed at Florence, and dedicated to the grand duke, in 1698. He was eſtabliſhed in the ſervice of his court, which, by very expenſive efforts, ſeems to have delighted in the exhibition of whatever the wild imagination of poets could invent. His works were brought on the different ſtages of Italy from 1657 to about 1680.

MONIKEDAM, or Monikendam, in *Geography*, a ſea-port town of Holland, on the river Monick, on the borders of the Zuyder ſee, with a ſmall port; nine miles N.E. of Amſterdam. N. lat. 52° 29′. E. long. 4° 52′.

MONILIA, in *Botany*, from *monile*, a necklace, alluding to the beaded appearance of the threads, which are ſuppoſed to be the ſeat of the fructification. Perſ. Syn. Fung. 691. Obſ. Mycolog. faſc. 2. t. 4. f. 8, 9. (Aſpergillus; Mich. Gen. 212. t. 91.)—Claſs and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eſſ. Ch. Stalked or diſperſed, fibrous. Threads beaded or jointed.

Perſoon defines 12 ſpecies of this minute, but curious genus. They are confounded by common obſervers, under the general idea of *Mucor*, or Mould, being found on various putrifying vegetable ſubſtances; ſometimes on the dung of animals. The author juſt mentioned diſpoſes them in three ſections, of which we ſhall cite an example or two.

Section 1. *Stalked; the threads collected into a round head.*

M. *glauca*. Perſ. n. 4. (Aſpergillus capitatus, capitulo glauco, ſeminibus rotundis; Mich. Gen. 212. t. 91. f. 1. Mucor glaucus; Linn. Sp. Pl. 1656. Fl. Dan. t. 777. f. 2.)—Tufted, of a glaucous grey.—Common on rotten apples, peaches, melons, &c. It forms tender greyiſh-white patches, of no determinate figure. When examined with a microſcope, each minute individual proves to be a globoſe *head of threads*, radiating in every direction, and ſupported by a long ſlender *ſtalk*. The texture is ſo tender and evaneſcent, that the plant cannot be preſerved.

M. *penicillus*. Perſ. n. 7. Obſ. Mycol. faſc. 2. 35. t. 4. f. 8, 9.—Cluſtered, lemon-coloured, permanent. Stalk downy. Threads even.—Found by Perſoon on the dung of mice, but very rarely. The texture is durable. *Stalks* rigid, ſhorter than the former, their height ſcarcely exceeding the diameter of the *head*. The *threads* are ſmooth, not beaded, forming an exception to the generic character, ſo that Perſoon juſtly doubts, whether this little plant be properly referred to *Monilia*. It can hardly however be reduced to any other known genus.

Section 2. *Cauleſcent; threads ſtraight, digitate.*

M. *digitata*. Perſ. n. 9. (Aſpergillus albus tenuiſſimus, graminis dactyloidis facie, ſeminibus rotundis; Mich. Gen. 215. t. 91. f. 3. Mucor cruſtaceus; Linn. Sp. Pl. 1656, with an erroneous quotation of Micheli's letter-preſs. M. penicillatus; Bull. v. 1. 107. t. 504. f. 11.)—Glaucous. Stalk ſimple. Threads finger-like.—Very common on all kinds of fermenting or corruptible ſubſtances, compoſing greyiſh uneven tufts, of an extremely delicate and minute ſtructure. The beaded *threads* ſtand four or five together, radiating, at the top of each common *ſtalk*. The latter is ſaid by Bulliard to be ſometimes branched.

Section 3. *Diſperſed, ſtemleſs; threads irregularly ſcattered, muſty.*

M. *antennata*. Perſ. n. 12. (Dematium antennæforme; Hoffm. Germ. Crypt. t. 13. f. 4. Aſpergillus cæſpitoſus, ex obſcuro nigricans, ſeminibus ovatis; Mich. Gen. 213. t. 91. f. 6?)—Diſperſed, black. Joints of the threads ovate.—Common in autumn on the trunks of trees, or on pales, which it renders black in patches. In ſummer it is ſaid by Perſoon to be, in a young ſtate, tender, more ſcattered, and almoſt of an olive colour.

Such minute productions as this, muſt neceſſarily be liable to confuſion. Thoſe who ſtudy *Conſervæ*, and look no further, would conſider the preſent as of that genus; Lichenographiſts might ſuppoſe it a *Collema*, deſtitute of fructification, or more probably a *Lepraria*, conſiſting of nothing elſe. The patient obſervers of theſe intricate works of creation do great ſervice in collecting them together, even under a confined or partial view of the ſubject, for the uſe of thoſe who can conſider it on a larger ſcale; becauſe every body cannot be ſo laboriouſly intent on every department of nature.

MONILIFERA, Vaillant's name for the *Oſteoſpermum* of Linnæus, alluding to the globoſe form and hard ſubſtance of its ſeeds, which are extremely ſingular in the claſs *Syngeneſia*. See Osteospermum.

MONIMASCA, in *Geography*, a town of Africa, in Cacongo, on the right bank of the Zaire. S. lat. 5° 55′. E. long. 12° 50′.

MONJOUL, a town of Hindooſtan, in Bahar; 45 miles E. of Hajypour. N. lat. 25° 34′. E. long. 86° 18′.

MONISTROL de Loire, a town of France, in the department of the Upper Loire, and chief place of a canton, in the diſtrict of Yſſengeaux; 19 miles N.E. of Le Puy. The place contains 3913, and the canton 10,453 inhabitants, on a territory of 192½ kiliometres, in five communes. N. lat. 45° 17′. E. long. 4° 13′.

MONITORY Letters, are letters of warning and admonition, ſent from an eccleſiaſtical judge upon information of ſcandals and abuſes within the cognizance of his court.

MONITOU Islands, in *Geography*. See Monetou.

MONJUIEH. See Mont-jouy.

MONJUR, a town of Aſiatic Turkey, in Caramania; 20 miles S. of Kirſhehr.

MONIY, a river of Brazil, which runs into the bay of Maranhao. S. lat. 2° 40′. W. long. 45° 29′.

MONK, George, in *Biography*, duke of Albemarle, was ſon of ſir Thomas Monk, and born in 1608. He received his education chiefly from the care of his maternal grandfather ſir George Smith, with whom he reſided. His father was in reduced circumſtances, and having ſubjected himſelf to an arreſt for debt, the ſon, indignant at the ſheriff's officer who came to ſerve the proceſs, aſſaulted and caned him without mercy. To avoid the conſequence of this outrage, he entered at the age of ſeventeen as a volunteer, under his

his relation fir Richard Greenville, then about to embark on an expedition againft the Spaniards. In this and a following enterprize the fuccefs was trifling, and in 1629 he went to ferve in the Low Countries, firft under lord Oxford, and then under lord Goring, the latter of whom advanced him to the rank of captain. During the following ten years he was prefent at various fieges and battles, and laid in a ftock of profeffional knowledge, which qualified him for a higher command. He returned home at the commencement of the civil wars, and was engaged in behalf of the king, but he appears, in a fhort time, to have fallen under fufpicion of being inclined to the caufe of parliament, and orders had been actually iffued to arreft him on his arrival, and his regiment was taken away. He was permitted to go on his parole to Oxford, where he completely juftified himfelf to the king, and was raifed to the rank of major-general in the Irifh brigade, then employed under lord Byron, in the fiege of Nantwich. He was foon made prifoner, and his whole brigade, by Fairfax, and being fent to the Tower of London, was kept in confinement till November 1646. He amufed himfelf, during his leifure, by compofing "Obfervations on military and political Affairs," which he fent in manufcript to lord Lifle, by whofe direction they were publifhed after his death. Through the intereft of this nobleman, Monk was liberated, on condition of taking the covenant; he went to Ireland, where he was appointed commander-in-chief for the parliament in the north of Ireland, and obliged O'Neal, who was at the head of a rebellion of the natives, to raife the fiege of Londonderry. The fuperiority of the royalifts, another party at that time in Ireland, and the unwillingnefs of the Scotch troops to act with thofe of the parliament, fo embarraffed him, that he found it neceffary to make a treaty with O'Neal, and to put Dundalk into the hands of the king's troops, after which he returned to England. The parliament was indignant at this termination, and paffed a vote of difapprobation of the treaty with O'Neal, but at the fame time fo far acquitted Monk, that it was refolved his conduct fhould not be enquired into. Monk probably never forgave this proceeding, though he foon after accepted a command in Scotland under Cromwell, who formed a regiment for him, and made him lieutenant-general of artillery. He performed feveral important fervices for the government, and when Cromwell left Scotland in purfuit of Charles II., Monk was left to command in that country at the head of 7000 men. In this ftation he acted with vigour and fuccefs: befieged and took Stirling caftle, whence he fent all the records of the kingdom to London. He ftormed Dundee, and, in imitation of Cromwell in Ireland, put the governor, and all the men in arms, to the fword. This example of favage feverity deterred other places from refiftance, and he became mafter of the whole country, with the exception of fome of the inacceffible parts of the Highlands. His health declined, and in 1652 he was obliged to go to Bath, but on his recovery he returned to Scotland, as one of the commiffioners for its union with the Englifh commonwealth.

The Dutch war, in the mean time, broke out, and in 1653 Monk was transferred to the fea-fervice. "He was now," fays Dr. Campbell, in his Lives of the Admirals, "nearly forty-five years of age, which feemed a little of the lateft to bring a man into a new fcene of life, yet it muft be remembered, that he was bred in a maritime country, and had ferved at fea in his youth; fo that the preferment was not abfolutely out of his way; or if it was, he foon made it appear that he could eafily accommodate himfelf to any fervice that might be beneficial to his country." In June 1653 he engaged, with the fleet of which he had the command, the Dutch fleet: and being on board the Refolution with admiral Deane, who in the very beginning of the action was killed by a chain-fhot, a new invention afcribed to De Witte, Monk with great prefence of mind threw his own cloak over the dead body, and having taken two or three turns on the deck, and encouraged the men to do their duty, ordered it to be removed into his cabin. The conteft lafted two days, and at length terminated in a complete victory obtained by the Englifh. Soon after Van Tromp had fitted out another fleet, with which, on the 29th of July, he engaged the Englifh under Monk. The Dutch admiral was killed in the action, and a moft decifive victory accrued to the Englifh, teftified by the capture or deftruction of more than thirty fhips, and the moment the refult was known the States General were obliged to fend their minifters here to conclude a peace upon any terms that could be obtained. At an entertainment fubfequent to the thankfgiving for this victory, Cromwell, now protector, with his own hand put a gold chain around the neck of his fuccefsful admiral. After this he was employed again in Scotland, and conducted the government with which he was entrufted, fo as to conciliate the perfonal good-will of the nation, however difaffected in their hearts, to the rule to which they were forced to fubmit. His former attachment to the royal caufe excited fome diftruft of him on the part of Cromwell, and fome hopes of him in the royalifts, but he was very cautious, and took care to give no ground of fufpicion by his actions. By his letters, and by his conduct, there feems now no doubt that he was fteadily and ftrongly attached to Cromwell, to whom he not only communicated all that he could difcover of the king's intelligence with others, but fent him alfo a copy of the letter, written by king Charles II. to himfelf, which for a confiderable time was confidered as a proof of Monk's early affection for the king's fervice, a fuppofition that is now clearly and abfolutely overturned. Cromwell, however, was fufpicious of him to the laft, and but a fhort time before his death he wrote the general, or admiral, a long letter, concluding with the following poftfcript, "which," fays the difcerning Campbell, "I conceive affords us a better picture of Oliver than is any where to be met with, and which is no lefs fingular, drawn by his own hand:"

P.S. "There be that tell me, that there is a certain cunning fellow in Scotland, called George Monk, who is faid to lie in wait there to introduce Charles Stuart. I pray you ufe your diligence to apprehend him, and fend him up to me."

Immediately on the death of Oliver, Monk proclaimed Richard, from whom he received a very kind letter, which among other things faid, "that his father had directed him to be governed chiefly by his advice." To this, Monk returned a prudent anfwer, but did not commit himfelf: he forefaw that Richard would not be able long to maintain his authority, and was unqueftionably preparing to act according to circumftances. But whatever were his private views, no politician could have kept them more clofely concealed. His relation and early patron, fir John Greenville, fent the general's brother to him in Scotland, with a letter from the king, foliciting his fupport; but though he received his brother with kindnefs, he fent him back with no confidential communication on the fubject. Lambert, his principal rival, was at this period poffeffed of the chief influence over the army in England. By direction of the Committee of Safety, who now held the reins of government, he marched northwards with the view of overawing Monk. The latter, to gain time, difpatched commiffioners to London to treat of an accommodation, and in the mean while the parliament refumed sumed its authority. Monk set out on his journey to the metropolis: his character was so highly estimated, that he received addresses on all sides requesting that he would use his influence, and exert his powers, in settling a legal and equitable government. On his arrival he took his quarters in Westminster, affecting a perfect and unlimited obedience to the existing parliament, and even caused some of their orders to be executed which revolted against his own mind. At length he complained of the odious service forced upon him, and required the House, in a peremptory manner, to issue writs for assembling a new and a free parliament. This was the death warrant to the long, or rump parliament, and the general rejoicings that were made on the occasion sufficiently proved the odium which that assembly had incurred with the nation. Every thing now manifestly tended to the restoration of monarchy, and yet Monk still maintained the appearance of attachment to republican principles, and allowed, at least openly, no channel of communication between him and the king. At length the general unbosomed himself to a person by the name of Morrice, a relation and intimate friend, and through his means sir John Greenville was admitted to a conference with the general, and entrusted with a verbal message to the king, consisting of assurances of fidelity, and advice for his conduct. Thus was the restoration begun, prosecuted, and perfected by Monk, who assisted, on the 8th of May, 1660, at the proclamation of Charles II. in the capital. On the landing of the king at Dover, he was met by the general, who was hailed by Charles and his brother with all the distinction justly due to one who had been so instrumental in the great event. It was unquestionably regarded as an additional benefit conferred on the sovereign, though perfectly unjustifiable on the part of Monk, that he discouraged and opposed all all those limitations of the royal power and prerogative which some of the best and most judicious friends to political liberty had proposed, and insisted that his restoration should be unconditional. His rewards, as was natural, soon followed, and they were as ample as a subject could expect. His titles, preferments, and fortune he received as favours from the king, all which he might, perhaps, have received in another way, as a very large party in the country would have gladly made him Oliver's successor, but as Campbell expresses it, "Monk generously despised a diadem to which he had no right, and with equal greatness of mind, refused to make any terms with him to whom it belonged, chusing to leave the king's power, and the people's freedom, to be discussed in the only assembly that could have a right to meddle with them." He was created a knight of the Garter, was admitted into the privy-council, made master of the horse, gentleman of the bed-chamber, first commissioner of the treasury, and created duke of Albermarle, with the grant of a landed estate of 7000*l. per annum*. His vast elevation he bore with the modesty and discretion that seemed to be inherent in his disposition. He sat as one of the commissioners for the trial of the regicides, an office which, it is hoped, he undertook with a view of moderating the ferocity of others connected with him, in the same commission. As for Monk, he conducted himself with at least the appearance of humanity in every case, except in the production of private letters from the marquis of Argyle on the trial of that nobleman, and for this he has been justly censured. The question respecting the production of these letters, to the prejudice of the marquis of Argyle, has been lately discussed with much eagerness. Mr. Fox, in his posthumous historical work, has no doubt of the fact, and he speaks of Monk, with that indignation which he was always known to feel for baseness and hypocrify. He says, "All depended upon the army, and that army had fallen into the hands of one, than whom a baser could not have been found in its lowest ranks. Personal courage appears to have been Monk's only virtue; reserve and dissimulation made up the whole stock of his wisdom." Mr. Rose endeavours to vindicate the character of the general, but his arguments are feeble, and his reasoning inconclusive. Mr. Serjeant Heywood, in his "Vindication of Mr. Fox's Historical Work," relates very fully and clearly the arguments, for believing that Monk was guilty of the charge imputed to him with respect to the unfortunate marquis. He proves, in the most satisfactory manner, that it is highly probable Monk did receive letters from Argyle which might affect his life, and then offers strong reasons to shew that he most likely produced them to the parliament, which was sitting in judgment on the marquis. Of Monk, the learned serjeant says, "though not guilty of the precise crime for which they [the regicides] were to be tried, he had waded to his dukedom through bloodshed, duplicity, and crimes." And he further adds, "he probably became the restorer of monarchy, only because he was disappointed in the hope of succeeding to the protectorate, on the abdication of Richard. He had recently acted with some of those who were brought before him for trial, and his crimes deserved the same punishment which he unblushing concurred in inflicting upon theirs." On this subject we refer our readers for more ample information to Heywood's "Vindication," and to the Monthly Review, vols. lix. and lxix. p. 366, 367.

Monk joined the lord chancellor Hyde in the constitutional measure of disbanding the army, with an exception in favour of his own regiment: and he was chiefly instrumental in the suppression of the insurrection of the Fifth-monarchy men. At the breaking out of the Dutch war in 1664, he exerted all his powers in refitting and manning the fleet, and was appointed joint-admiral of the fleet with prince Rupert. The two commanders put to sea in April 1666, and fell in with the Dutch under the younger Tromp and De Ruyter. By the duke's advice prince Rupert took a division of the fleet to oppose that of the French, which was coming to the aid of the Dutch. The English was now much inferior in number to their enemy, but the duke of Albermarle did not hesitate to begin the attack on the 1st of June, and a most bloody engagement ensued, which lasted four days. On the first three, the English, much inferior to the enemy, were obliged to make a retreating fight, the duke himself closing the rear, with the full resolution of blowing up his ship rather than be taken. On the fourth, the return of prince Rupert enabled the English to face about, and a fresh action ensued, at the end of which they retired to their harbours, having been on the whole the principal sufferers. A new combat, by the same commanders on both sides, on the 25th of July, ended to the disadvantage of the Dutch; after which the duke of Albermarle came home and struck his flag. The daring enterprize of the Dutch in 1667, who sailed up the Thames, and burnt some ships at Chatham, called forth the exertions of this veteran once more, who exposed himself to danger in their defence. At this time he was much out of health, being affected with symptoms of dropsy, which put a period to his life, in January 1670, in the 62d year of his age. His remains were deposited, with great funeral pomp, in Henry VIIth's chapel, in Westminster Abbey. Biog. Brit. Hume's Hist. Stockdale's edition of Campbell's Lives of the Admirals, vol. ii.

Monk, anciently denoted a person who retired from the world to give himself up wholly to God, and to live in solitude and abstinence.

The

The word is derived from the Latin *monachus*, and that from the Greek μοναχος, *solitary*, of μονος, *solus, alone;* because the ancient monks lived in solitude, as the true monks still do.

Such were the hermits and anachorets, who withdrew into deserts, and lived remote from all commerce of mankind.

Some writers, as father Helyot, (Differt. Prelim.) trace the origin of monks up as early as the time of the Therapeutæ; and maintain, that there had been an uninterrupted succession of monks from the Therapeutæ to St. Anthony. Others, on the contrary, are contented with going back as far as St. Paul the Hermit.

The original of monks seems to have been this. The persecutions which attended the first ages of the gospel, forced some Christians to retire from the world, and live in desarts and places most private and unfrequented, in hopes of finding that peace and comfort among beasts, which were denied them among men. And this being the case of some very extraordinary persons, their example gave so much reputation to retirement, that the practice was continued when the reason of its commencement ceased. After the empire became Christian, instances of this kind were numerous, and those, whose security had obliged them to live separately and apart, became afterwards united into societies. We may also add, that the mystic theology, which gained ground towards the close of the third century, contributed to produce the same effect, and to drive men into solitude for the purpose of enthusiastic devotion.

In this kingdom many persons might seek this kind of refuge, during the persecution of Diocletian about the year 303, and in those perilous and afflictive times, when the Romans oppressed the Britons, and when their situation was rendered more distressing by the invasion of the Scots from Ireland, the Picts and Attacots from the north, and the Saxons and Franks from the east and south.

The monks, at least the ancient ones, were distinguished into *solitaries*, *cœnobites*, and *sarabaites*.

The solitary are those who live alone, in places remote from all towns and habitations of men, as do still some of the hermits.

The cœnobites are those who live in community with several others in the same house, and under the same superiors.

The sarabaites were strolling monks, having no fixed rule or residence.

The houses of monks again were of two kinds, *viz. monasteries*, and *lauræ*. See MONASTERY, and LAURA.

Those we call monks now-a-days are cœnobites, who live together in a convent or monastery, who make vows of living according to a certain rule established by the founder, and who wear a habit which distinguishes their order.

Those that are endowed, or have a fixed revenue, are most properly called monks, *monachi;* as the Chartreux, Benedictines, Bernardines, &c. The Mendicants, or those that beg, as the Capuchins and Franciscans, are more properly called *religious*, and *friars;* though the names are frequently confounded.

The first monks were those of St. Anthony; who, towards the year 305, formed them into a regular body, engaged them to live in society with each other, and prescribed to them fixed rules for the direction of their conduct. These regulations, which Anthony made in Egypt, were soon introduced into Palestine and Syria by his disciple Hilarion. Almost about the same time, Aones, or Eugenius, with their companions Gaddanas and Azyzas, instituted the monastic order in Mesopotamia, and the adjacent countries; and their example was followed with such rapid success, that, in a short time, the whole East was filled with a lazy set of mortals, who, abandoning all human connexions, advantages, pleasures, and concerns, wore out a languishing and miserable life amidst the hardships of want, and various kinds of suffering, in order to arrive at a more close and rapturous communication with God and angels. From the East this gloomy institution passed into the West, and first into Italy and its neighbouring islands; though it is uncertain who transplanted it thither. St. Martin, the celebrated bishop of Tours, erected the first monasteries in Gaul, and recommended this religious solitude with such power and efficacy, both by his instructions and his example, that his funeral is said to have been attended by no less than 2000 monks. From hence, the monastic discipline extended, gradually, its progress through the other provinces and countries of Europe. There was, however, a great difference in point of austerity between the western and oriental monks; for the former could never be brought to bear the severe rules to which the latter voluntarily submitted; and the reason of this difference may be partly derived from the nature of the respective climates in which they dwell. The European countries do not so much abound with delirious fanatics, and with persons of a morose and austere complexion, as those arid regions that lie towards the burning east; nor are our bodies capable of supporting that rigid and abstemious method of living, which is familiar and easy to those who are placed under a glowing firmament, and who breathe in a sultry and scorching atmosphere. It was, therefore, the name, more than the thing itself, that was transported into the European countries; though this name was indeed accompanied with a certain resemblance or distant imitation of the monastic life instituted by Anthony and others in the East. There were besides the monks of St. Basil, called in the East, *Calogeri*, from καλος γερων, *good old man*, and those of St. Jerom, the hermits of St. Augustine, and afterwards those of St. Benedict and St. Bernard, at length came those of St. Francis and St. Dominic, with a legion of others; all which see under their proper heads, BENEDICTINES, &c.

Towards the close of the fifth century, the monks, who had formerly lived only for themselves in solitary retreats, and had never thought of assuming any rank among the sacerdotal order, were now gradually distinguished from the populace, and endowed with such opulence and honourable privileges, that they found themselves in a condition to claim an eminent station among the supports and pillars of the Christian community. The fame of their piety and sanctity was so great, that bishops and presbyters were often chosen out of their order; and the passion of erecting edifices and convents, in which the monks and holy virgins might serve God, in the most commodious manner, was at this time carried beyond all bounds. However, their licentiousness, even in this century, was become a proverb; and they are said to have excited the most dreadful tumults and seditions in various places. The monastic orders were at first under the immediate jurisdiction of the bishops, from which they were exempted by the Roman pontiff, about the end of the seventh century; and the monks, in return, devoted themselves wholly to advance the interests, and to maintain the dignity of the bishop of Rome. This immunity which they obtained was a fruitful source of licentiousness and disorder, and occasioned the greatest part of the vices with which they were afterwards so justly charged. In the eighth century the monastic discipline was extremely relaxed both in the eastern and western provinces, and all efforts to restore it were ineffectual. Nevertheless, this kind of institution was in the highest esteem, and nothing could equal

equal the veneration that was paid, about the close of the ninth century, to such as devoted themselves to the sacred gloom and indolence of a convent. This veneration induced several kings and emperors to call them to their courts, and to employ them in civil affairs of the greatest moment. Their reformation was attempted by Lewis the Meek, but the effect was of short duration. In the eleventh century they were exempted by the popes from the authority of their sovereigns, and new orders of monks were continually established; insomuch that in the council of Lateran, that was held in the year 1215, a decree was passed, by the advice of Innocent III. to prevent any new monastic institutions, and several were entirely suppressed. In the fifteenth and sixteenth centuries, it appears from the testimonies of the best writers, that the monks were generally lazy, illiterate, profligate, and licentious epicureans, whose views in life were confined to opulence, idleness, and pleasure. However, the reformation had a manifest influence in restraining their excesses, and rendering them more circumspect and cautious in their external conduct.

Monks are distinguished by the colour of their habits into *black*, *white*, *grey*, &c. Among the monks, some are called monks *of the choir*, others *professed* monks, and others *lay* monks; which last are destined for the service of the convent, and have neither clericate nor literature.

MONKS, *Cloistered*, are those who actually reside in the house; in opposition to *extra-monks*, who have benefices depending on the monastery.

Monks are also distinguished into *reformed*, whom the civil and ecclesiastical authority have made masters of ancient convents, and put in their power to retrieve the ancient discipline, which had been relaxed; and *ancient*, who remain in the convent, to live in it according to its establishment at the time when they made their vows, without obliging themselves to any new reform.

Anciently, the monks were all lay-men, and were only distinguished from the rest of the people by a particular habit, and an extraordinary devotion. Not only the monks were prohibited the priesthood, but even priests were expressly prohibited from becoming monks, as appears from the letters of St. Gregory. Pope Syricius was the first who called them to the clericate, on occasion of some great scarcity of priests, that the church was then supposed to labour under: and since that time the priesthood has been usually united to the monastical profession.

MONKS, *Professed*. See PROFESSED.

MONKS, *Proprietary*. See PROPRIETARY.

MONK-*Fish*, called also *Angel-fish*, in *Ichthyology*, a species of *squalus*. See SQUALUS *Squatina*.

MONK'*s-Hood*, a name given to several species of aconite, or wolf's-bane. See ACONITUM.

MONK'*s-Rhubarb*. See RHUBARB, and RUMEX.

MONK'*s-Seam*, among *Sailors*, is, when the selvedges of sails are laid a little over one another, and sewed on both sides.

MONKAH, in *Geography*, a town of Bengal; eight miles S. of Palamow.

MONKEARY, a town of Bengal; 20 miles S.S.E. of Palamow.

MONKEDOO, a town on the W. coast of Borneo. S. lat. 2° 40'. E. long. 109° 51'.

MONKEY, in *Zoology*, a name given by way of distinction to those apes which have tails; the others, or those without tails, being more properly called *apes*.

The same distinction holds in Latin, the tailed ones being called *papiones* or *baboons*, when they have short tails; *cercopitheci*, when their tails are longer; and those without tails *simiæ*. See CERCOPITHECUS and SIMIA.

MONKEY *of the West Indies*. See GUARIBA, and SIMIA *Beelzebub*.

MONKEY, *Green*. See CALLITRICHUS, and SIMIA *Sabæa*.

MONKEY, in *Ship Building*, a machine for driving bolts where more force is required than the common method, by a mall. It is composed of a long pig of iron traversing in a groove, or in a frame, with handles, with a groove on the underside, and slides upon a ridge of iron fixed in a bed. The whole is fixed to centre the bolt to be driven, and then the monkey is forcibly drawn, to strike the bolt, by ropes and pulies.

It also denotes the stand for the pinion and winch-handle, which draw the lock-paddles in a canal, &c. *Plate* V. *Canals*, *fig*. 38 and 39, *k*, *k*.

MONKEY-*Boat*, a name sometimes applied to a long narrow sort of boat.

MONKEY-*Blocks*, in *Ship-Building*. See BLOCKS.

MONKEY'*s-Bread*, in *Gardening*. See ADANSONIA.

MONKEY-*Flower*, the common name of a flower plant. See MIMULUS.

MONKEY-*Island*, in *Geography*, a small island in Currituck sound, near the coast of North Carolina. N. lat. 36° 22'. W. long. 76 4'.

MONKEY-*Key*, a small island in the bay of Honduras, near the coast of Mexico. N. lat. 16 25'. W. long. 89° 35'.

MONKEY-*Point*. See PUNTA *Chica*.

MON-KIEU-TCHIN-HOTUN, a town of Corea. N. lat. 43° 1'. E. long. 129 50'.

MONKTON, a post-town of America, in Addison county, Vermont, E. of Ferrisburg; containing 1080 inhabitants.—Also, a township of Annapolis county, in Nova Scotia, inhabited by Acadians, and a few families from New England; it consists chiefly of wood-land and salt-marsh, and contains about 60 families.

MONLIRAS, a town of the island of Cuba; 45 miles E. of Bayamo.

MONMOUTH, a large maritime county of New Jersey, in the United States, of a triangular shape; 80 miles in length, and from 25 to 40 in breadth; it is divided into six townships, and contains 19,872 inhabitants, including 1633 slaves. The face of the country is generally level, with few high lands, the most noted of which are Navesink and Centre-hill. The soil is for the most part sandy; but other parts are fertile. At the mouth of Navesink river there is a curious cave, now in a ruined state, 30 feet long, and 15 wide, containing three arched apartments.

MONMOUTH, or *Freehold*, a post-town and capital of the fore-mentioned county, situated 22 miles N.E. by E. of Allentown, 34 E. of Trenton, and 64 N.E. by E. of Philadelphia. It contains a court-house, gaol, and a few compact dwelling houses, with a Presbyterian and Baptist meeting-house.

MONMOUTH, a post-town of Lincoln county, on the E. side of Androscoggin river; 49 miles N. of Portland, containing 701 inhabitants.

MONMOUTH, *Cape*, lies on the E. side of the straits of Magellan.

MONMOUTH-*Island*, one of the four islands of Royal Reach, in the straits of Magellan, and the second from the westward.

MONMOUTH-*Island*, one of the Bashee islands in the East Indian sea.

MONMOUTH, a market-town and borough in the hundred of Scenfreth and county of Monmouth, England,

land, ſtands on a narrow peninſula, formed by the confluence of the rivers Monnow and Wye. It is a town of great antiquity, and according to Horſley (in his Britannia Romana) was the Bleſtium of Antoninus. No Roman remains, however, have been found here to corroborate this opinion, which, though probable, is chiefly founded on the fact of the coincidence of diſtances between that and the connecting ſtations, northward and ſouthward, with the actual diſtances between thoſe and the preſent ſcite of Monmouth. The caſtle at this place is mentioned in ancient records as being one of the ſtrong holds garriſoned by the early Saxons, to ſecure their conqueſts of the country between the Severn and the Wye; and to curb the depredatory incurſions of the Welſh. Very little, however, beſides this bare fact, is known concerning this fortreſs, till the era of the Norman conqueſt, when it appears, from a paſſage in Domeſday book, to have belonged to the king. William, the ſon of William Fitz-Baderon, to whom four "carucates of land in the caſtle of Monmouth, part of the royal demeſne, were given in cuſtody" about this time, took the ſurname of de Monmouth, from the place, which continued in the poſſeſſion of his deſcendants till the reign of Henry III., when John de Monmouth became the proprietor. During the reign of that monarch, which is recorded to have been one continued ſcene of civil ſtrife, this fortreſs was occaſionally beſieged and occupied by both parties; and was ultimately reſigned, together with the honour, to prince Edward and his heirs for ever, in conſideration of certain lands granted for life. The prince ſoon afterwards ſurrendered it to the king, who beſtowed it on his younger ſon Edmund, earl of Lancaſter, from whom it deſcended to John of Gaunt, king of Caſtile and duke of Lancaſter, who, as well as his ſon, Henry of Bolingbroke, (afterwards Henry IV.) made it their favourite reſidence. Henry V., the celebrated hero of Agincourt, was born in one of the rooms of Monmouth caſtle in the year 1387, and ſeems alſo to have paſſed his infancy here. This caſtle ſubſequently became the property of Henry VI. as part of the duchy of Lancaſter, which had deſcended to him by inheritance. Upon his dethronement and attainder, it fell to Edward IV., who granted it to William, lord Herbert, whom he created earl of Pembroke; but having once more reverted to the crown, Henry VII. poſſeſſed it by the ſame right that he aſcended the throne. Since that period, the caſtle has become private property, but at what date its alienation from the duchy took place is not aſcertained. Previouſly, however, to the cloſe of the 17th century, we find it in the poſſeſſion of Henry, the firſt duke of Beaufort, and it is now the property of his illuſtrious deſcendant, the preſent duke.

Under the auſpices of its lords, Monmouth early became a privileged place, and particularly enjoyed many immunities as forming a parcel of the duchy of Lancaſter. The earlieſt charter, however, which appears in the archives, is dated in the year 1549, and was granted by the monarch then reigning "to the burgeſſes of his burgh and town of Monmouth, in the marches of Wales, and within his duchy of Lancaſter." This deed confirms various franchiſes and privileges beſtowed upon the inhabitants by Henry VIII.; and in addition confers the power of electing a mayor and two bailiffs. Since that time therefore Monmouth has been governed by officers under that denomination, who are aſſiſted by a common council, compoſed of eighteen members.

The ſituation of this town is extremely pleaſant and highly pictureſque: it ſtands near the extremity of an expanded vale, ſurrounded by gentle hills and ſwelling eminences, either covered to their ſummits with rich woods, or laid out in fields of corn and paſture. It is a place of conſiderable extent, and contains many reſpectable buildings, but has only one principal ſtreet, which leads from the bridge over the Monnow, to the market place. In this ſtreet ſtands the town-hall, an edifice of modern erection, built upon pillars, which form a handſome colonnade. A ſtatue of Henry V. is placed in a niche over the front entrance. The other ſtreets are moſtly narrow. One of them leads from the market place to St. Mary's church. That edifice formerly belonged to an alien priory for black monks of the Benedictine order, an inſtitution which was founded in the time of Henry I. by Wihenoc, grandſon of Fitz-Baderon and third lord of Monmouth. Only a few veſtiges of the monaſtery can now be diſcovered a little to the north of the church, which, with the exception of the tower and ſpire, is entirely a new building. The church of St. Thomas, now ſubordinate to St. Mary's, is an ancient ſtructure. Coxe, in his hiſtorical tour through this county, ſays, "that the ſimplicity of its form, the circular ſhape of the door-ways, and of the arch ſeparating the nave from the chancel, and the ſtyle of their ornaments, which bear a Saxon character, ſeem to indicate that it was built before the conqueſt." Some authors even ſuggeſt, that there is a probability of the more ancient parts being of Britiſh origin. It is certainly, for Wales, a moſt curious ſpecimen of early architecture; and in no mean degree deſerves the attention of the antiquary, particularly the ſemicircular arch of the northern door-way.

The county gaol is a new maſſive edifice, well adapted to its purpoſe; the apartments are airy; and much attention is paid to the health and morals of the priſoners. This building ſtands at one extremity of the town, on the banks of the Monnow. Here is a free ſchool founded by William Jones in the reign of James I.; alſo an alms-houſe for 20 poor people, eſtabliſhed and endowed by the ſame individual.

The remains of walls, lines of circumvallation, curtains, baſtions, and other works of defence, clearly ſhew that this town muſt have been, at one time, a ſtrongly fortified place, and from its ſituation, there is little doubt but it might eaſily be made ſo again. On thoſe ſides which were unprotected by the river, it has been evidently environed by ſtrong walls, and a deep foſſe capable of being filled with water. It had four gates, only one of which is now ſtanding. The ſuburb of St. Thomas was defended in the ſame manner as the town, with which it communicated, as now, by a ſtone bridge with baſtion-towers on each ſide thrown over the Monnow. There are two other bridges in the immediate vicinity of the town, the Wye-bridge and Tibb's-bridge; the former of which is conſtructed of ſtone, and the latter of wood.

The ruins of the caſtle of Monmouth, the ancient reſidence of its powerful lords, are diſcovered occupying the ridge of an eminence ſituated between the market place and the river Monnow. From a view of theſe it is evident, that this fortreſs has been the work of ſeveral and even diſtant periods. Some portions of them beſpeak a Saxon if not a Roman origin, while others are of a date poſterior to the reign of Henry III. The maſſive ſtructure of part of the walls is particularly remarkable, being from ſix to ten feet thick, and are compoſed of pebbles and liquidated cement, ſo cloſely compacted as not to yield in hardneſs to ſtone itſelf. The chamber, in which king Henry was born, is wholly demoliſhed, but ſome of the beams, which ſupported the flooring, ſtill remain viſible. Adjoining to it is a large apartment, which probably formed the baronial hall, and was afterwards uſed for the county aſſizes till about the

middle

middle of the laſt century. A handſome domeſtic edifice, conſtructed of ſtone, ſtands in the middle of this vaſt pile of ruins. From the date over the principal door it appears to have been built in 1673, for the occaſional reſidence of the Beaufort family. Two hoſpitals, founded here by John de Monmouth about the year 1240, are now entirely levelled with the ground.

The manufactures of Monmouth, at the preſent period, are trifling; ſo that the inhabitants are chiefly ſupported by the navigation of the river Wye, the trade with Hereford and Briſtol, the ſupply of the neighbouring diſtrict with various kinds of ſhop-goods, and the number of perſons of independent fortune, who reſide either conſtantly or occaſionally in the town, or its vicinity. The paring and cleanſing of bark brought from the foreſts of the Upper Wye, for the purpoſe of exportation, conſtitutes, during the ſeaſon, the employment of a number of men, women, and children among the lower ranks. But though fallen in reſpect of its manufacturing importance now, Monmouth ſeems to have carried on a very conſiderable trade ſome centuries ago.

Monmouth caps are celebrated by Shakſpeare in his play of Henry V.; "If your majeſties is remembered of it, the Welſhmen did goot ſervice in a garden, where leeks did grow, wearing leeks in their Monmouth caps." Fuller likewiſe praiſes them highly, by calling them the moſt "ancient, general, warm, and profitable coverings of men's heads in this iſland." The old ballad of the caps, printed in "The Antidote againſt Melancholy," ſays,

"The ſoldiers that the Monmouth wear,
On caſtles' tops their enſigns rear."

Monmouth has ſent one member to parliament ſince the reign of Henry VIII. The right of election is in the burgeſſes inhabitants, in conjunction with the burgeſſes inhabitants of the towns of Newport and Uſk, as decided by the houſe of commons on a petition of right in 1680. According to the parliamentary returns of 1801, the population of this town then amounted to 3345 perſons, but Mr. Coxe, in his "Hiſtorical Tour," fixes it at about 2600 ſouls.

The vicinity of this town diſplays much beautiful and intereſting ſcenery. The views from the high conical hill, called the Kymin, are particularly fine, extenſive, and diverſified. A walk leads to the ſummit of this hill, which terminates in a level plain crowned with a wood, through which ſix viſtas have been cut. Each of theſe exhibits in fine perſpective a rich, grand, and varied proſpect, of an expanſive tract of country. In the centre of the wood, a pavilion, intended for a naval monument, has been lately erected by ſubſcription. It is a circular edifice, conſiſting of two ſtories, and built in the form of an embattled tower. The frieze round it is ornamented with medallions of the moſt eminent Britiſh admirals, accompanied with emblematical and appropriate devices. The view from the ſummit of this pavilion is perhaps the fineſt and moſt extenſive in England, embracing a circumference of nearly 300 miles, and including within its range all the materials of ſublime and beautiful ſcenery.

Troy-houſe, the ancient ſeat of the family of Herbert, and afterwards of that of Somerſet, is ſituated about a mile from the town on the banks of the Trothy, from which river its name is corruptly derived. Of the original edifice few traces can now be diſcovered, except an old gate-way with a pointed arch. The preſent manſion was built under the direction of the celebrated Inigo Jones, but though well proportioned and commodious, it poſſeſſes no features of peculiar beauty. This place was formerly much famed for its excellent and luxuriant gardens, particularly in the time of Charles I. when they were the property of ſir Thomas Somerſet, brother to the marquis of Worceſter. Two miles weſt from hence is a Treowen, the ſeat of the Jones family, but now converted into a farm-houſe. In the pariſh of Lanvihangel Tavanbarch', at the diſtance of three miles to the north, ſtand the remains of Grace-Dieu abbey, which was founded by John of Monmouth in the year 1229. In the pariſh of Landeilo Creſſeney appear the magnificent ruins of White Caſtle, anciently called Lanteilo caſtle, or Caſtell-Gwin. This fortreſs, at the time of the conqueſt, formed part of the poſſeſſions of Brian-Fitz-count, earl of Hereford, from whom it came, firſt to the Cantalupes, and afterwards to the Braoſes. Coxe's Hiſtorical Tour through Monmouthſhire, 4to. 1801. Beauties of England and Wales, vol. x.

MONMOUTHSHIRE, one of the weſtern counties of England, is bounded on the ſouth-eaſt by the Severn ſea or Briſtol channel; on the weſt by Glamorganſhire and part of Brecknockſhire; on the north by part of the latter county, and that of Hereford; and on the eaſt by Glouceſterſhire. It extends about 33 miles in length, and 20 in breadth, and compriſes, according to the lateſt ſurveys, an area of 550 ſquare miles, or 352,000 acres. By the returns made to parliament in 1801, it contained 9365 houſes, and a population of 45,582 inhabitants. The whole county is now divided into ſix hundreds: Scenfreth, Abergavenny, Wentloog, Caldecot, Uſk, and Raglan; and comprehends 127 pariſhes, and ſeven towns. The latter are Monmouth, Caerleon, Chepſtow, Uſk, Abergavenny, Newport, and Pontypool. All the pariſhes, with reſpect to eccleſiaſtical juriſdiction, are included in the province of Canterbury, and alſo in the dioceſe of Landaff, with the exception of ſix, *viz.* Welſh-Bicknor, Dixon, and St. Mary's being in the dioceſe of Hereford; and Oldcaſtle, Llanthony, and Cwmyoy, belong to St. David's.

At the period of the Roman invaſion Monmouthſhire formed part of the territory inhabited by the Silures, who, beſides this diſtrict, poſſeſſed the counties of Glamorgan, Brecknock, Radnor, Hereford, and ſuch parts of Glouceſterſhire as lay between the Severn, the Teme, and the Towy. On the diviſion of Britain into provinces by the Romans, this county was included in Britannia Secunda. From the period at which theſe illuſtrious conquerors left our iſland, till the eſtabliſhment of the Saxon heptarchy, the hiſtory of Monmouthſhire, in common with that of almoſt every portion of Britain, is uncertain and contradictory. In the legends of theſe times, however, it makes a moſt conſpicuous figure. Many of the heroic exploits of Uther Pendragon, and of the celebrated Arthur, are ſaid to have taken place within its boundaries. Caerleon was long the capital of the Britiſh dominions, and is frequently deſcribed by the bards as equalling Rome in ſplendour and magnificence. After the full eſtabliſhment of the Saxon power in England, this county ſeems to have formed a petty principality of itſelf, under the name of Gwent, whoſe princes were ſometimes bold enough to aſpire at independence, but who, for the moſt part, paid tribute to the princes of South Wales. The invincible courage which had marked their character at a more remote period, ſtill continued in full force during this era, and oppoſed a moſt effectual barrier to the attempts of the Saxon monarchs to ſubjugate the principality. Canute, the Dane, entered Gwent with a powerful army, in the year 1034, but though he defeated Rytherch-ap-Jeſtin, prince of of South Wales, he was unable to hold poſſeſſion of the country. It was not, indeed, till the reign of Edward the Confeſſor, that the Gwentians could be regarded as conquered, when Harold, having penetrated into the heart of Wales, forced the inhabitants to ſwear fealty to the crown of England, and retained military poſſeſſion of this county, in order the more effectually to ſecure the advantages he had gained. The Norman invaſion, however, was the ſignal to all the Welſh tribes for renewing the war, and throwing off the yoke which had been thus impoſed. In order again to reduce them, the conqueror, too politic to weaken his own army in ſuch a warfare as Wales preſented, encouraged his powerful barons to make incurſions into that country at their own expence, and with their own retainers, and, as a reward, granted them the privilege of holding the lands they conquered in capite. Monmouthſhire was accordingly overrun in this way after a long and bloody ſtruggle for its independence; but the conquerors having built numerous caſtles and fortreſſes in order to overawe the inhabitants, ſoon began, in their turn, to arrogate to themſelves an independent authority. Continual diſputes took place betwixt them, with reſpect to the extent and boundaries of their lands, which not unfrequently terminated in open hoſtility to each other, and even to the crown of England. The power poſſeſſed by theſe barons marchers, within the limits of their property, was little inferior to that of a prince. They held courts and adminiſtered juſtice at will to their tenants and dependants, in all queſtions both civil and criminal. This ſyſtem of juriſprudence, perhaps the moſt wretched and deplorable that could poſſibly be adopted, continued in this county, as well as in the other marches of Wales, till the reign of Henry VIII., when the government of the lords marchers was aboliſhed, and Monmouthſhire was detached from the principality, and included among the counties of England. The ſtatute, however, authoriſing this change, does not ſeem to have been immediately acted upon, for we find Monmouth regarded as a Welſh county ſo late as the reign of Charles II., when it firſt began "to be reckoned an Engliſh county, becauſe the judges kept the aſſizes here on the Oxford circuit." From this circumſtance it is difficult to fix, preciſely, the period at which Monmouthſhire might be ſtrictly conſidered as an Engliſh county: probably, however, not before the juriſdiction of the ſupreme "court of lords marchers," uſually held at Ludlow, was finally aboliſhed in the firſt year of William and Mary.

The general aſpect of Monmouthſhire preſents to the eye a continual recurrence of hill and dale, wood and water, corn fields and meadows; "the ſublime of wildly magnificent, and the beauty of mild and cultivated ſcenery combine to delight the traveller at every turn he makes in this uncommonly diverſified diſtrict." Nor is the air leſs favourable to health, than the face of the country is intereſting to the view. Except on the more elevated ridges, which are no doubt cold and bleak, it is, for the moſt part, mild and temperate. It is a remarkable circumſtance, that the fogs here, during winter, ſhift periodically; ſo that it is no uncommon thing to ſee the hills enveloped ſeveral days with a thick fog, while the valley beneath has the ſplendour of a genial ſun: but on a ſudden theſe effects are entirely reverſed; the fog deſcends into the valley, and the mountains are, in their turn, left open to the rays of heaven. Monmouthſhire abounds with rivers, of which the principal are the Severn, the Wye, the Uſk, the Rumney, the Monnow, or Mynwy, and the Ebwy. The Wye is particularly remarkable for the beauty and variety of its ſcenery, exhibiting a continued ſeries of enchanting views, which have been amply deſcanted on by Gilpin, Ireland, Warner, and many other touriſts; and latterly by Bloomfield, in a poem expreſsly devoted to the ſubject. (See WYE.) The Uſk likewiſe diſplays many charming ſcenes, and when ſwelled by mountain torrents ſpreads itſelf out into expanſive lakes, and occaſionally inundates the adjacent country. This river is navigable for barges up to Tredonnoc-bridge. There is only one canal in this county, which was begun in 1792, and finiſhed in 1798. It enters Monmouthſhire from Brecknockſhire, and divides it nearly into two equal parts, paſſing in its courſe cloſe to the towns of Abergavenny and Pontypool, and falls into the eſtuary of the Uſk at a ſhort diſtance below Newport. About a mile above that town, a branch ſtrikes off to Cramlin-bridge, near Llanhiddel, where it terminates. Still further to facilitate the conveyance of the more weighty articles which this county produces, rail-roads have been formed in different parts of it. One, which connects the iron-works at Blaenavon with the canal at Pontnewydd, is particularly remarkable. It only extends five miles and a quarter in length, and riſes no leſs than 610 feet. The roads in Monmouthſhire, with the exception of thoſe from New-Paſſage to Newport, Caerdiff, and Uſk, and thence to Abergavenny, were, till lately, proverbially bad; and though improved, are capable of ſtill further amendment.

Monmouthſhire, conſidered in an agricultural point of view, may be properly divided into three diſtricts. The firſt, compriſing the ſouthern part of the county, conſiſts, almoſt entirely, of moor, or marſh lands, with a portion of meadow-grounds. The ſecond diviſion, which takes in the eaſtern line of the county, is particularly fertile. The third diviſion forms the weſtern and moſt hilly part of the county. The kinds of corn generally raiſed are wheat, barley, and oats, with a very ſmall proportion of peas and beans. Theſe are, of courſe, principally produced in the eaſtern diviſion, the other two being much more paſtoral, or grazing, than farming diſtricts. The cattle reared are oxen, ſheep, and mules. The firſt are principally bred in the northern parts, and fed in the ſouthern. Theſe generally grow to a large ſize, are extremely docile, and well fitted for the labours of the field. The ſheep are naturally of an inferior kind, but the ſtock has been greatly improved of late years, by various croſſes with the Coteſwold, Southdown and Dorſet breeds. Mules are very abundant here, and are a peculiarly fine race, ſtrong in the bone, and of exquiſite ſymmetry, running from fourteen to ſixteen hands high, and are ſo valuable as to ſell for thirty or forty pounds each. The breed is conſtantly kept up to its priſtine ſtandard of excellence by the importation of ſtallion aſſes from Spain. But whether this traffic ſhould be encouraged is extremely doubtful, conſidering the ſuperior qualifications of the horſe, the breeding of which animal is, in conſequence, almoſt wholly neglected in this county. Indeed the Monmouthſhire horſes are by far the moſt miſerable race of their ſpecies in our iſland, neither adapted for the ſaddle, nor uſeful for agricultural purpoſes.

Monmouthſhire was formerly celebrated for its manufacture of ſtockings and knit caps, but that trade almoſt entirely diſappeared ſoon after the eſtabliſhment of the iron works in the reign of queen Elizabeth. Since that period the iron buſineſs, though in different degrees at different times, has conſtituted the chief employment of the manufacturing claſſes in the county. This branch of trade has of late years increaſed to a prodigious extent, ſo that Monmouthſhire will, in all probability, ſoon take the precedence, as an iron diſtrict, of every other county in Great Britain.

At

At Pontypool and at Usk there are still considerable manufactories of japanned goods, generally distinguished by the name of Pontypool ware, because first invented in that town, but this trade has suffered much from the competition of Birmingham, joined to the unfavourable state of our foreign relations. The commerce of Monmouthshire, which is very considerable, is almost entirely confined to the towns of Chepstow and Usk: under these respective names the reader will find the different articles of export mentioned. See Newport and Usk.

Monmouthshire, to the antiquary, is particularly interesting: Caerwent was first the capital of the Silurian dominions, and afterwards a Roman station. The other stations of that people in this district were Isca-Silurum at Caerleon, Gabannum at Abergavenny, Burrium at Usk, and Blestium at Monmouth; but some antiquaries place the two last at Oldcastle and at Caerphilly. To trace the direction of the Roman roads, particularly of the Julia Strata, in their passage through this country, is a subject of much difficulty. This has arisen chiefly from the disagreement of antiquaries with respect to the point at which the legionary troops usually crossed the Severn, which some have fixed at Amesbury, and others at Oldbury, Aust, New Passage, Henbury, and Portishead. The Julia Strata is most distinctly visible in the vicinity of Caerwent, running in the direction of Penhow. A few traces of it can likewise be discovered near Caerleon and Newport, but its course between these towns is wholly uncertain. Mr. Evans, however, conjectured that it proceeded along the right bank of the Usk, leaving Malpas church on the west, and Crindahouse on the east, and passed to the scite of St. Woolo's church, on the hill north of Newport, where is a large encampment, and a tumulus, now nearly destroyed, which Mr. Harris regarded as an *arx speculatoria*. Of the roads which struck off from the Julia Strata, one led from Isca-Silurum to Burrium, where dividing into two ramifications, one proceeded to Gobannium and the other to Blestium. Another has evidently run in a south-westward direction, from Abergavenny to Neath, or to some station in Gloucestershire. This road is called by the natives *Sarn-hir*, or the long paved causeway, and in the neighbourhood of Bydwelly still remains almost entire. Besides these, various other marks of Roman civilization have been discovered in this county at different periods, consisting of aqueducts, baths, tessellated pavements, columns, statues, bas-relievos, sudatories, hyppocausts, altars, votive and sepulchral stones, sarcophagi, urns, medals, coins, fibulæ, &c. Numerous encampments of different forms and sizes are likewise distributed over this county, some of them no doubt originally British, and afterwards altered by the Romans, Saxons, or Danes, and others of them originally Roman, and altered in the same way by the warriors of a later period. A few seem to be Saxon or Danish entirely. Castles and other places of more permanent defence, are no less frequent here than encampments. Several of these have claims to very high antiquity, but the precise period of their erection is unknown. The most distinguished among them are the castles of Caerleon, Usk, and Scenfreth, which are said to be of British origin. The rest are no doubt of a much later date, and most probably not earlier than the period of the Norman conquest. Some of the churches in this county are very ancient, as appears from the style of their architecture, the circular arch, and the crenellated and billetted moulding for which they are so conspicuous, being characteristic of the Saxon and early Norman eras. The custom of whitewashing these edifices is unhappily too much practised here, and destroys the venerable appearance which they would otherwise display. The disgusting and highly injurious practice of burying in churches is likewise extremely prevalent in Monmouthshire.

In concluding this article, it may be remarked, that though Monmouthshire is an English county, the inhabitants more generally speak the Welsh than the English language, particularly in the north-western and south-western districts. Their manners and customs bear a very strong resemblance in every respect to those of the principality. They display the same antipathy to the language and manners of the English, and an attachment to their own ancient practices. Catholics are very numerous in this county, and not only they, but the Protestants also, retain many vestiges of Romish superstition. Thus the custom of begging bread for the souls of the departed, still continues to be practised, on All-Souls' day, among the lower orders. A very interesting and satisfactory account of the antiquities, scenery, &c. of this county, will be found in Coxe's "Historical Tour in Monmouthshire," 4to.

MONNEROU, a small island in the channel of Tartary, between the island of Saghalien, and the continent. N. lat. 46° 20'. E. long. 142° 21'.

MONNIER, Peter le, in *Biography*, an eminent professor of philosophy, was born at Vire, in Normandy, about the year 1685. By his talents he became professor in the college of Harcourt, at Paris, and was elected a member of the Royal Academy of Sciences. He died Nov. 27, 1767. He was author of "Cursus Philosophicus," in six volumes 12mo., which was made a text-book in many of the French colleges. Monnier contributed also a variety of papers, that form a part of the "Memoirs" of the academy of which he was a member. He left behind him two sons, inheritors of his abilties, and both of them admitted to seats in the Academy of Sciences, of whom the eldest is the subject of the following article; the youngest, Lewis William, was made physician to the king at St. Germain-en Laye. Du Fresnoy.

Monnier, Peter-Charles le, a celebrated French astronomer, was born at Paris in 1715. From a very early period of his life he devoted himself to the study of astronomy, and is said to have made very accurate observations when he was only sixteen years old. At the age of twenty he had the high honour of being nominated a member of the Royal Academy of Sciences at Paris. At this period he accompanied Maupertuis in his expedition to Lapland for the purpose of measuring a degree of latitude. In 1748 he went to Scotland, to join lord Macclesfield in observing an annular eclipse of the sun, and he was the first astronomer who had the satisfaction to measure the diameter of the moon on the sun's disk. The king of France, Lewis XV., was much attached to astronomy, and patronized those who successfully pursued that science; and it is said he not only respected, but honoured and even loved Le Monnier. "I have seen the king," says Lalande, "come out of his cabinet, and look around for Le Monnier, and when his younger brother was presented to him, on his appointment to the office of first physician, his majesty was pleased to wish him the merit and reputation of his brother the astronomer." Monnier was always with the king when he observed the remarkable celestial phenomena. Thus they were together to witness the two transits of Venus, in the year 1761 and 1769. While these important observations were making, at which the celebrated La Condamine was present, the king was particularly careful not to disturb, by the smallest motion, the astronomers in their occupation. It is so described fcribed by the aftronomer himfelf, in his differtation on the fubject; "His majefty," fays he, "perceiving that we judged the laft contacts to be of the greateft importance, a moft profound filence, at that moment, reigned around us." In the year 1750, Le Monnier was directed to draw a meridian-line at the royal chateau of Bellevue, where the king was accuftomed to make his obfervations. On this occafion Lewis prefented him with fifteen thoufand livres, which the aftronomer expended in inftruments, with which he afterwards made his beft and moft important obfervations. The king had already prefented him with a beautiful houfe at Paris, where he refided till the revolution, and purfued his aftronomical labours. Le Monnier was inceffant in his application to his favourite fcience, and apparently unwearied in thofe obfervations which tended to perfect it. Le Monnier was the preceptor of Lalande, and was worthy of fuch a fcholar, as the fcholar was of his inftructor. Le Monnier forefaw in young Lalande, when he was but fixteen years old, the acute, learned, and indefatigable aftronomer. When Lalande was fent to Berlin in 1742, to make obfervations for the purpofe of determining the parallaxes of the moon, Le Monnier lent him his five feet mural quadrant. Le Monnier died at Lizieux, in Normandy, on the fecond of April 1799, at the advanced age of eighty-four years. He was ardent in his friendfhips, but his hatred was implacable. Lalande once difpleafed him, and he could never after regain his favour, but his pupil's gratitude and refpect for him were always the fame, and were, on every occafion, publicly declared. In 1797, Lalande wrote an eulogium on Le Monnier for the "Connoiffance des Temps," in the language of gratitude, refulting from fentiments of profound veneration and efteem for the venerable aftronomer, but Le Monnier refufed to read it. This great man left behind him a number of valuable MSS. with fome good obfervations. He had by him a feries of lunar obfervations, and a multitude of obfervations of the ftars, which he had announced as early as the year 1741, but he refufed to publifh them, nor could the moft earneft entreaties of thofe whom he moft efteemed, lead him to alter his intentions. Annual Regifter 1799. See LE MONNIER.

MONNIERIA, in *Botany*, fo named by Lœfling and Linnæus, in honour of M. le Monnier, firft phyfician to the French king Louis XV., who accompanied Caffini through the fouthern provinces of France, in the fummer of 1739, and fubjoined an account of their natural hiftory, particularly their more curious plants, to the geometrical remarks of that aftronomer. M. le Monnier was greatly inftrumental in promoting the introduction of hardy exotics into France. He had a choice garden at Verfailles, where the writer of this vifited him in 1786, and a very extenfive and valuable herbarium. Of the time of his death we have no information. Another genus had been previoufly dedicated to this able botanift, by Bernard de Juffieu; but this was reduced by Linnæus, and fubfequent writers, to *Graticla*. Mr. R. Brown has however re-eftablifhed it, under the appellation of HERPESTIS; fee that article, and GRATIOLA.—Lœfl. It. 197. Linn. Gen. 363. Schreb. 480. Willd. Sp. Pl. v. 3. 856. Mart. Mill. Dict. v. 3. Juff. 421. Lamarck Dict. v. 4. 261. Illuftr. t. 596.—Clafs and order, *Diadelphia Pentandria*. Nat. Ord. uncertain; fufpected by Juffieu and Lamarck to be near the *Borragineæ*, (*Afperifoliæ* of Linnæus,) or poffibly akin to *Spigelia*. We perceive ftrong indications of the *Euphorbiæ* in fome of its characters, however difcordant others may appear.

Gen. Ch. *Cal.* Perianth inferior, in five deep, unequal, permanent fegments; the upper one longeft, linear, incurved over the flower; the lateral one on the outer fide lanceolate, half as long, the reft ftill fhorter and obtufe. *Cor.* of one petal, fhorter than the upper fegment of the calyx, ringent; tube cylindrical, narroweft in the middle, curved; upper lip ovate, obtufe, undivided; lower in four equal, parallel, ftraight, oblong, obtufe, deep fegments. Nectary an ovate fcale, at the bafe of the germen, within the lower filament. *Stam.* Filaments two, dilated, membranous; the uppermoft concave, cloven at the extremity; the lowermoft flat, three-cleft; anthers on the upper filament two, combined, hairy within, embracing the ftigma; on the lower three, very minute, cylindrical, probably fterile. *Pift.* Germen fuperior, roundifh, five-angled, five-lobed; ftyle folitary, thread-fhaped; ftigma capitate, oblong, flattened within, orbicular, fharp-edged. *Peric.* Capfules five, ovate, fhort, compreffed, of one cell, divided half way down into two valves. *Seeds* folitary, ovate, tubercular, filling the capfule, ftraighter and blunter at their inner margin, each enclofed in a tunic, of two fmooth elaftic valves.

1. M. *trifolia*. Linn. Sp. Pl. 986. Aubl. Guian. v. 2. 730. t. 293.—Gathered by Lœfling at Cumana in South America; by Aublet in the meadows and cultivated land of Cayenne and Guiana. A fpecimen, fent by Mr. Alex. Anderfon, from the Dutch fettlements in the laft-mentioned country, was given us by fir Jofeph Banks, there being none in the Linnæan herbarium. The *root* is annual and fibrous. *Stem* about a foot high, repeatedly forked, leafy, round; the upper part rough with minute hairs, curved upward. *Leaves* ternate, on hairy ftalks, the lower ones oppofite, the reft ufually alternate; leaflets nearly equal, above an inch long, ovate, entire, pale green, hairy, efpecially the edges and ribs, thickly befprinkled on both fides with fmall refinous dots; the middle one flightly ftalked. *Flowers* in terminal, folitary, cloven, divaricated, fimple clufters, rather than fpikes, with a folitary flower between, at the bafe. *Calyx* hairy. *Corolla* white. The *leaves*, though they have been dried 20 years, retain an acrid or burning flavour, without any fragrancy.—The natural affinity of this rare plant has puzzled the greateft botanifts. We venture to hint its relationfhip to the *Euphorbiæ*, rather as a conjecture than otherwife. The *capfules* are pale, dotted like the leaves. *Seeds* dark grey, almoft black, rough with prominent points. S.

MONNOYE, BERNARD DE LA, in *Biography*, was born at Dijon in the year 1641. He was brought up to the bar, but his tafte and eagernefs for polite literature gave him difguft for legal purfuits. He contented himfelf therefore with a very trifling office, the duties of which gave him an opportunity to employ much time in his favourite ftudies. He acquired an accurate knowledge of the Greek, Latin, Spanifh, and Italian languages, and attained confiderable excellence in the compofition of French poetry. In 1671, he obtained a prize of the French academy for a poem entitled "Le Duel aboli." Several of his other pieces, written in praife of Lewis XIV., obtained fimilar honours. He was free from ambition, and notwithftanding the celebrity which he had acquired, he preferred living in his native province to a refidence in the capital. He paffed his time in an eafy ftate of independence, till the fatal fyftem of Law reduced him, with thoufands, to abfolute poverty. (See LAW.) In this fituation his merit was not overlooked; his diftrefs was alleviated by a penfion from the duke of Villeroi, and he lived to the advanced age of eighty-eight. He was extremely converfant with literature in all its branches, and was accounted the oracle of bibliographers of his time. The works by which he is principally known are "Poefies Francoifes,"

coifes," and "Nouvelles Poesies," which consist of miscellaneous pieces of different degrees of merit. There are annexed to them Latin poems and small pieces which may be ranked with fables, epigrams, and tales, written with elegance and true classical simplicity, but many of them have a licentious tendency. The Latin poems were also published by the abbè d'Olivet, together with those of Huet, Massieu, and Fraugier; "Noels Bourguignons," a set of Christmas carols in the Burgundian dialect, much applauded for their humour, but on account of the grossness of some of them, they were condemned by the Sorbonne. Monnoye was author also of "Remarques sur le Menagiana avec une Dissertation sur le Livre De tribus Impostoribus;" "Remarques sur les Bibliotheques de du Verdier et de la Croix-du-Maine." He was editor of "Recueil des Pieces choisies." His own works have been printed in three vols. 8vo. Moreri.

MONOCASY, in *Geography*, a river of America, in Maryland, which, after a S.S.W. course, discharges itself into the Patowmac, about 50 miles above Georgetown.

MONOCEROS, UNICORN, in *Astronomy*, a southern constellation formed by Hevelius, containing in his catalogue, nineteen stars, and in the Britannic Catalogue thirty-one. See CONSTELLATION.

MONOCEROS, in *Ichthyology*, a species of *monodon;* which see.—Also, a species of *Balistes*, with the fin of the head unirradiated, and the caudal rays carinated. This is the *Balistes unicornu* of Bloch, with 51 rays in the anal fin, the *Capriscus longus*, &c. of Klein, and the Acaramucu of Marcgrave and Willoughby. There is a variety of this, or a distinct genus of *Balistes*, denominated *Scriptus β*, the unicorn fish of Bahama, described in Catesby's Carolina. It is found in the sea that washes the coasts of Asia and South America; its colour is varied with cinereous and brown; the first is somewhat more than a foot in length; the second is three feet long; they feed on young crocodiles, and the latter is held to be poisonous.

MONOCEROS, a name which has been given to several animals, among which are, the *unicorn*, generally supposed to be a fabulous animal, but the existence of which, in the interior of Africa, is insisted upon by several writers. A Mahometan African prince is said to have sent two of them to Mecca in the year 1799; an insect called Meloë monoceros by Linnæus, and Notoxus monoceros by Fabricius. See the preceding article.

MONOCHORD, a musical instrument with which to try the variety and proportion of musical sounds.

The monochord, according to Boethius, is an instrument invented by Pythagoras, for measuring geometrically, or by lines, the quantities and proportions of sounds.

The ancient monochord was composed of a rule divided and subdivided into divers parts, on which there was a string pretty well stretched upon two bridges, at each extremity. In the middle between both was a moveable bridge, called *magas*, by means of which, in applying it to the different divisions of the line, the sounds were found to be in the same proportion to one another, as the divisions of the line cut by the bridge were.

The monochord is also called the *harmonical canon*, or *canonical rule;* because serving to measure the degrees of gravity, and acuteness of sounds. Ptolemy examines his harmonical intervals by the monochord.

There are also monochords with divers strings, and a multitude of fixed bridges; but the use of all these may be supplied by one single moveable bridge; by only shifting it under a new chord or string, which is placed in the middle, and represents the entire sound, or open note, answering to all the divisions on the other bridges.

When the chord was divided into equal parts, so that the terms were as 1 and 1, they called them unisons; if they were as 2 to 1, octaves, or diapasons; when they were as 3 to 2, fifths, or diapentes; if they were as 4 to 3, they called them fourths, or diatessarons; if the terms were as 5 to 4, diton, or a greater third; if as 6 to 5, demi-diton, or a lesser third; lastly, if as 24 to 25, demi-diton, or diesis.

The monochord, being thus divided, was probably what they call a system, of which there were many kinds, according to the different divisions of the monochord.

Dr. Wallis has taught the division of the monochord in the Philosophical Transactions; but that instrument is now disused, the modern music not requiring such division.

Censorinus informs us that Apollo found the monochord in the sound of the string of his sister Diana's bow; and it seems at least probable, that the first stringed instrument was a monochord, and that that single string was the string of a bow.

Aristides Quintilianus says that the monochord was recommended by Pythagoras on his death-bed as the musical investigator, the criterion of truth. It appears to have been in constant use among the ancients, as the only means of forming the ear to the accurate perception, and the voice to the true intonation of those minute and difficult intervals which were then practised in melody.

MONOCHORD, Μονοχορδος, formed of μονος, *solus, single,* and χορδη, *chord*, is also used for any musical instrument, consisting of only one chord or string.

The monochord, called also the *vielle*, and vulgarly the *hurdy-gurdy*, has frets which are raised by the action of the fingers on a row of keys; and instead of a bow, the string is made to vibrate by the motion of a wooden wheel: there is also a second string serving as a drone, producing always the same sound: this is furnished with a bridge loosely fixed, which strikes continually against the sounding board, and produces a peculiar nasal effect. The trumpet marine, or trumpet Marigni, was a string of the same kind, which was lightly touched at proper points, so as to produce harmonic notes only: it was impelled by a bow. The Æolian harp is also an instrument, which, when agitated by the wind, affords a very smooth and delicate tone, frequently changing from one to another of the harmonics of the string, according as the force of the wind varies, and as it acts more or less unequally on different parts of the string. See ÆOLUS's *Harp*.

MONOCHROMA, Μονοχρωμα, compounded of μονος, *single*, and χρωμα, *colour*, a picture all of one colour.

MONOCOLI, Μονοκωλοι, a kind of fabulous men, who, as the Arabians give out, inhabit the country of Segir, in Arabia Felix; and are but half formed.

The word is Greek, compounded of μονος, *one*, and κωλον, *a member*.

MONOCOTYLEDONES, in *Botany*, from μονος, *one*, and κοτυληδων, *a cotyledon*, or *seminal leaf*, one of three great tribes or assemblages of plants, into which the whole vegetable kingdom is divided, by botanists who study a natural system of arrangement, the other two being the ACOTYLEDONES and DICOTYLEDONES; see those articles, especially the latter. Some plants indeed have been esteemed polycotyledonous, as Flax, and the Fir tribe. But these are so very few, and agree so perfectly in their nature and physiology with the *Dicotyledones*, that they are best comprehended under the same

ſame denomination. The only vegetables for which we ſhould be diſpoſed to eſtabliſh a claſs of *Polycotyledones*, are the Ferns and Moſſes, hitherto referred, by Juſſieu and his followers, to the *Acotyledones*, but phyſiologiſts are not agreed on the ſubject of the germination of theſe plants. (See FILICES and MUSCI). A ſtill greater difficulty exiſts as to a diſtinction between the *Monocotyledones* and the *Acotyledones*, to which we have already ſufficiently adverted; ſee COTYLEDONES and GERMINATION. We ſhall therefore here conſider thoſe two ſuppoſed families as but one, for which the denomination of *Acotyledones* would be the moſt proper of the two, the other term having originated in an old opinion, that what is now known to be the *albumen* of the plants in queſtion, (and was obſerved in palms and graſſes, which make a part of the number,) was really a ſimple cotyledon.

But although we conſider the above two families as but one, as far as concerns the preſence, or rather abſence, of a cotyledon, we mean not to ſay the *Fungi*, *Algæ*, and *Hepaticæ*, which make the firſt three orders of Juſſieu's *Acotyledones*, have any conſiderable affinity to thoſe of his orders which he refers to *Monocotyledones*. On the contrary, they are, as well as the *Filices* and *Muſci*, his 4th and 5th orders, ſo very diſtinct, that no ſyſtem which combines them all together can be called natural. As to his remaining order of *Acotyledones*, the *Naiades*, they are too heterogeneous for us to decide upon with any certainty; but their natural affinity to the *Monocotyledones* of Juſſieu, and their diſſimilitude to his *Acotyledones*, are equally obvious. In the following remarks therefore we wiſh to be underſtood as ſpeaking of thoſe natural orders which the great French botaniſt comprehends under his diviſion of *Monocotyledones*, though we conſider them as not having properly any cotyledon at all. Theſe are fixteen in number, *Aroideæ*, *Typhæ*, *Cyperoideæ*, *Gramineæ*, *Palmæ*, *Aſparagi*, *Junci*, *Lilia*, *Bromeliæ*, *Aſphodeli*, *Narciſſi*, *Irides*, *Muſæ*, *Cannæ*, *Orchideæ*, and *Hydrocharides*. Under the laſt however Juſſieu, by miſtake, comprehends ſome dicotyledonous plants.

The plants in queſtion are remarkable for a great ſimplicity or plainneſs of ſtructure. Their leaves are for the moſt part alternate, ſimple, with ſimple parallel ribs. The number three prevails in the parts of fructification inſtead of five, which belongs to the *dicotyledones*. Their germination is lateral; their interior ſubſtance peculiarly ſoft and cellular. It is a favourite hypotheſis of Juſſieu that theſe flowers have no corolla, the gorgeous integument of the liliaceous plants being conſidered by him as a coloured calyx. His arguments in ſupport of this opinion only prove the great ſimplicity, and want of decided diſtinction, in their ſeveral parts. Thus, the petal of a tulip is alike liable to become half leaf, or half ſtamen. The outſide of petals of lilies, however richly they may be adorned within, in many inſtances approaches to the colour and texture of a calyx; while in *Pancratium* and *Narciſſus*, there is a ſuperabundance, or doubling as it were, of the more delicate part of the flower, ſo that theſe genera, far from wanting a corolla, appear to have two.

The internal ſtructure of the *Monocotyledones*, as explained by the learned Desfontaines and Mirbel, is extremely peculiar, and differs very eſſentially from that of other plants. They have no proper bark and wood, augmented gradually by concentric layers. (See CORTEX, and CIRCULATION *of the Sap*). Their cuticle indeed is like that of the *Dicotyledones*, generally ſpeaking; except that in ſome it abounds with a flinty ſecretion, in no ſmall quantity, nor is that ſecretion always confined to the cuticle; witneſs the order of graſſes. Their woody ſubſtance is depoſited round their numerous longitudinal tubes, as ſo many centres, ſuch tubes uniting here and there, compoſing a ſort of network, which gives firmneſs and tenacity to the body of the plant. Indeed the depoſition of wood, though not in concentric layers, is regular, according to ſome determinate arrangement in each family, and in ſeveral acquires a great degree of denſity and hardneſs. The peculiar ſecretions of this tribe are very frequently of a ſaccharine nature; and ſcarcely ever of a mucilaginous, never, we believe, of a reſinous kind. In their conſtitutions, ſome of them are very tender with regard to cold, others, in every reſpect nearly, the moſt hardy of plants; all are generally of rather rapid growth, though ſome very long-lived. Their roots are very generally perennial, to which there is ſcarcely an exception, beſides what occur in the natural order of graſſes. In conſideration of the order laſt mentioned, the *Monocotyledones* deſerve to be conſidered as the moſt important of all plants for the ſupport of mankind.

MONOCULUS, in *Entomology*, a genus of inſects of the order Aptera, of which the generic character is as follows: legs from four to eight, formed for ſwimming, and very long; body covered with a cruſt or ſhell divided into ſegments; ſome have four, ſome two antennæ, and ſome are without any; it has *one* or *two* eyes, notwithſtanding its name *monoculus;* when there are two eyes they approximate and are fixed in the ſhell; there are four feelers, in continual motion when ſwimming; the hind ones are very ſmall, and hook-ſhaped.

There are fixty-eight ſpecies, ſeparated into eight diviſions, named according to the firſt eight letters in the alphabet. Theſe are found chiefly in Europe, a few in India, commonly in muddy ditches, frequently in ſea-waters, often paraſitic on fuci, confervæ, ulvæ, and other aquatic plants. Many inhabit our own ditches or ſea-coaſts.

Of all the monoculi by far the greater part are very ſmall water inſects, requiring the aſſiſtance of the microſcope for the inveſtigation of their particular organs; ſome, however, as we ſhall ſee, are ſo large as to require no very minute inſpection, and one ſpecies is of a ſize ſo gigantic that it is generally conſidered as the largeſt of the whole cruſtaceous tribe. This is the polyphemus, and will be found in the diviſion G.

The inſects in diviſion A have a ſingle eye and cruſtaceous body.

Species.

OCULUS. In this ſpecies there are no antennæ, but two feelers, which are long and branched; the tail is inflected. The inſects of this ſpecies are found in the pools and ſtagnant waters in many parts of Europe; they ſwim in ſwarms upon their back; each inſect has a large black eye, which appears to occupy the whole of the head.

* QUADRICORNIS. The antennæ in this ſpecies are four; the tail is ſtraight and bifid, the diviſions are branched. It is deſcribed in Donovan's Engliſh Inſects. It is found in different parts of Europe, and in the ſtagnant waters of this country. The body is ſometimes greyiſh or greeniſh, ſmooth or covered with hair; it has eight legs that are hairy; the female poſſeſſes an oval bag, containing the eggs on each ſide the tail. This is a very minute inſect, it derives its ſpecific name from its four horns, and is well known, being very common in almoſt every ſtagnant water, and ſometimes makes its appearance in that of pumps and wells, and is accordingly obſervable frequently in water brought to table.

Its

Its ſize is not greatly ſuperior to that of the common mite.

MINUTUS. Here the antennæ are two and linear; the tail ending in two briſtles. This inſect is found at the banks of ditches, generally among duck-weed, and at firſt ſight is thought to reſemble the Lepiſma ſaccharina. The number of legs is ten, which are long and hairy; the tail ends in two papillæ.

CÆRULEUS. Antennæ two, linear; body blueiſh, with a ſtraight two-lobed tail. It inhabits Germany in muddy ditches. The head, the tail, and antennæ are red; the eyes black; abdomen green; legs eight.

* RUBENS. Antennæ two, linear; body reddiſh, with a ſtraight forked tail. Found in ditches and rivulets, and is common through the whole year; it has eight legs.

LACINULATUS. In this the antennæ are two, linear and white; tail curved forked. It inhabits Germany, in ditches.

LONGICORNIS. Antennæ two, linear and very long; tail bifid. It inhabits the ſea round Finmark. The tail ends in two briſtles.

CAPTIVUS. Antennæ two, linear; head covered with a dilated ſhield; tail ſtraight cleft. This is found in Germany. It has ſix legs; and the tail has ſix joints.

MINUTICORNIS. In this the antennæ are two, ſhort and linear; the tail is cleft and ending in two briſtles. It is ſometimes though not often found in ſea-water. The feelers are about half as long as the antennæ.

CLAVIGER. The antennæ two, ſubclavate, rigid; tail bifid. It inhabits, though very rarely, the rivers of Germany, and glides ſlowly along, alternately on its back, ſides, and belly, and ſometimes it will raiſe itſelf upright. The body above is white, and red beneath; the tail is without joints, and the legs are eight.

CRASSICORNIS. The antennæ two, dilated and ſhort; tail bicuſpidate. Sometimes found in marſhy places. The body is in five ſegments; the antennæ branched at the baſe.

CURTICORNIS. Antennæ two, which are minute and ſtraight, with three hairs at the tip; the body is inarticulate; the hands unarmed; the tail forked.

CHELIFER. Antennæ two, ſhort and recurved; body inarticulate; hands chelate; tail forked. Found in ſea-water.

BREVICORNIS. Antennæ two, thoſe of the male hooked; the tail is ſet with very ſhort briſtles. It inhabits ſea-marſhes, and reſembles the quadricornis. The antennæ of the female are forked at the tip.

The inſects in diviſion B have a ſingle eye and bivalve ſhell; the antennæ are branched.

Species.

* PULEX. Tail inflected; ſhell mucronate behind. This inſect derives its ſpecific name, *pulex* or *water-flea*, on account of its peculiar ſtarting or ſpringing motion; it is almoſt an univerſal inhabitant of ſtagnant waters, appearing ſometimes in ſuch vaſt ſwarms as to cauſe an apparent diſcolouration of the water. It is an inſect of a highly ſingular and elegant appearance, exhibiting, when magnified,, a beautiful diſtribution of internal organs. It is generally about $\frac{1}{10}$th of an inch in length, but ſometimes conſiderably larger. It is of an oval ſhape, ſomewhat truncated in front, and ſharply pointed behind; the body is incloſed in a bivalve tranſparent ſhell, which, when examined by the microſcope, appears finely reticulated. The eyes of theſe animals are of a ſingular conſtruction, they are large in proportion to the inſect, and placed very near each other, and appear to conſiſt of many ſeparate globules of a black colour, united under a common ſkin. In the female inſect the ovarium is generally very conſpicuous, filling the greater part of the ſpace between the ſhells; the ova are very large in proportion to the ſize of the animal, and the young are hatched before their excluſion from the parent. This animal is ſaid to poſſeſs, in an inferior degree, the ſurpriſing property of the genus aphis, *viz.* that of producing a ſeries of already impregnated deſcendants.

LONGISPINUS. Tail inflected; ſhell ſerrulate before and prickly behind. Found in freſh water. The ſhell is ovate, white, and pellucid, ending behind in a ſtrong ſpine ſerrate each ſide, and half as long as the ſhell; it has eight legs.

QUADRANGULA. The tail is inflected; ſhell quadrangular unarmed. Found in ſtagnant pools; the body is ſometimes red, and it has ſix legs.

SIMUS. Tail inflected; ſhell oval unarmed; found in marſhes; the ſhell is pellucid and yellowiſh.

RECTIROSTRIS. Tail inflected; hind head with two projecting horns: inhabits marſhes. The ſhell is oval pellucid, with gaping valves, and ciliate on the fore-margin; the tail two long briſtles; legs ſix to eight.

CURVIROSTRIS. Tail inflected; the front has two inflected horns. It is found in pools; the ſhell is hairy on the fore-margins; front has two pendent horns; the tail ends in two hooks; it has eight legs.

* MUCRONATUS. Tail inflected; ſhell ovate, beneath inflected, and prickly behind. It is found in marſhes. Swims on its back on the ſurface of the water. The ſhell has four black dorſal ſtreaks; it has twelve legs.

CRYSTALLINUS. Tail inflected; oblong cryſtalline; head with two ſhort horns at the tip. Found in freſh water. The body is white pellucid, with twelve hairy legs.

PEDICULUS.. The tail of this ſpecies is inflected. It inhabits freſh water.

SETIFER. The tail is ſtraight; ſhells with long tufts of hair at the angles of the valves. It inhabits ſtagnant pools. The ſhell is oblong, pellucid, and cryſtalline; the antennæ have three branches; the legs, which are eight or more, are very hairy; and the tail is divided at tip.

The inſects in diviſion C have a ſingle eye and bivalve ſhell; the antennæ are ſimple.

Species.

VIRIDIS. Shell ovate, downy, green; the fore-legs falcate, and ſerrate within. It is found in ſea-water on fuci and confervæ.

* LUTEUS. Shell ovate, gibbous, glabrous, pale yellow. Found on fuci.

* FLAVIDUS.. Shell oblong, glabrous, pale yellow. It is found frequently on the Fluſtra lineata. The ſhell is pellucid; fore-legs round.

GIBBOSUS. Shell ovate, hiſpid, and gibbous each ſide. Found on ulvæ. The ſhell is ovate, pale, and briſtly.

COARCTATUS. Shell ovate, glabrous, and contracted in the middle. It inhabits fuci. The ſhell is of a greeniſh hue, with a black eye.

The inſects in diviſion D have a ſingle eye and bivalve ſhell; antennæ tufted at the tip.

Species.

DETECTUS. Shell oblong, white, pellucid; tail with two briftles. Inhabits ditches. It has four legs, the fore ones are recurved; hind-ones reflected.

STRIGATUS. Shell kidney-fhaped, brown, with three white bands. Found in muddy ruts. The fhell is glabrous; the antennæ have eleven briftles.

ORNATUS. The fhell of this fpecies is ovate, fituate beneath, on the fore-part, and variegated with white, green, and fulvous.

PILOSUS. The fhell is ovate, brown, ciliate before and behind. This fpecies is found in the nectaries of the Utricularia minor. The fhell is fmooth, glabrous, and opaque.

CANDIDUS. Shell ovate, fnow-white, immaculate. It is found in marfhes. Shell obtufe before and behind.

LÆVIS. Shell ovate, glabrous, greenifh. Inhabits ditches. The fhell is obtufe and opaque; tail ending in a fpire.

VIDUA. Shell ovate, white, with three black bands. Found in muddy water. In this fpecies two of the bands are in the middle, and one on the fore-margin. The valves are gibbous and whitifh.

TELEMUS. Shell fub-globular, three-toothed behind with a truncate lip on the fore-part. It is found at Algira, and is pellucid. Some naturalifts imagine that it does not belong to this genus.

LENTICULARIS. Shell compreffed and lentiform. Found in Finland.

* CONCHACEUS. Shell ovate, downy. Found in ftagnant water. This is an Englifh infect, and has been defcribed and figured by Mr. Donovan. The body is green, opaque, with yellowifh legs; its abdomen nearly two-lobed, and fulvous, with a black circle in the middle: it contracts itfelf within the fhell, and fwims on the belly.

FASCIATUS. The fhell is oblong, whitifh, with a green band. Found in ftagnant water, and refembles a grain of barley. The green band is placed in the middle behind the eye.

MONACHUS. Shell glabrous, yellow, edged with black; the fhell is opaque, truncate before, and rounded behind.

CRASSUS. Shell oblong, gibbous, yellowifh, with an oblique, abbreviated, fulvous band. It inhabits fenny places.

Infects in divifion E with a fingle eye and univalve fhells, and two antennæ.

* SATYRUS. Shell ovate, pellucid, and emarginate behind; antennæ obtufe. This fpecies is noticed by Baker and Adams on the microfcope. The fhell is flat and membranaceous; fore-legs with a double fhank; tail truncate, and cleft in the middle.

SILENUS. Shell is ovate, opaque, and fub-marginate behind; laft joint of the antennæ fubulate. It is found in ditches filled with the leaves of trees. The fhell is fometimes yellowifh.

MÆNUS. Shell oval; antennæ horizontally extended; body truncate at the bafe. Inhabits fea-water. Swims on its back; fhell with a convex fulvous back.

FAUNUS. Shell ovate, pellucid, and emarginate behind; laft joint of the antennæ fubulate. Found in ditches among duck-weed. Shell gibbous; antennæ bent back.

BACCHUS. The fhell is ovate, emarginate behind, and ending in two briftles. It inhabits rivers. The antennæ are ftretched forwards.

THYAS. The fhell of this fpecies is dilated, linear; the antennæ are incumbent. Found in ftinking fea-water. The fore-legs are branched.

BRACTEATUS. The fhell is globular, and unarmed; it has fix legs. Is found in frefh water. The antennæ are obtufe; fhell very pellucid.

* SALTATORIUS. Shell oval-oblong, and briftly behind. This is defcribed by Baker and Adams. The fhell is pellucid, and terminated by briftles.

Infects in divifion F have their fhells univalve, and two eyes placed beneath.

CHARON. Shell pellucid, and four legs. Found in ditches. The eyes are fpherical, remote, deep black, with four capillary circles round them.

* DELPHINUS. Shell gibbous; eight legs. Inhabits rivers. It is defcribed by Baker on the microfcope.

ARMIGER. This fpecies has fix legs.

Infects in divifion G have their fhells bivalve; two eyes placed on the back.

Species.

POLYPHEMUS. Shell orbicular; the future lunate, and toothed behind; tail fubulate, and very long. This fpecies is commonly diftinguifhed by the title of molucca, or king-crab. Specimens have fometimes been feen two feet in length, exclufive of the tail. It is a native of the Indian ocean, and is generally found in pairs. The colour of the whole animal is of a yellowifh-brown; the fhell is very convex, rounded in front, and lunated behind, where it joins the lower part of the body. The fhell, which is of a cruftaceous nature, is marked on each fide into feveral fpiny incifions. It has feven legs on each fide, which are fituated beneath the concavity of the large or round part of the fhell, and are each terminated by a double claw; the branchiæ, or refpiratory organs, are difpofed in the form of feveral flat, rounded, imbricated lamellæ, on each fide the lower part of the body; the tail, which is ftraight, triangular, and of the fame cruftaceous nature with the reft of the fhell, is equal in length to the whole body, and gradually tapers to a fharp point. The eyes in this fpecies are diftant from each other, of a femi-lunar form, and the furface is divided into a great number of minute conical convexities: this part is, however, regarded as conftituting the cornea, or exterior covering of the eye, the organs themfelves being placed on a pedicle, beneath each of the femi-lunar corneæ. A writer in the Philofophical Tranfactions, fpeaking of this infect, fays, "the eyes, inftead of being approximated, as is required in the Linnæan generic character, are extremely diftant from each other, being fituated towards the fides of the fhell. The whole ftructure of the animal is very remarkable, and particularly his eyes, which are between the fourth and laft pair of claws on each fide, reckoning from his mouth, and excluding the fmall pair there placed, are inferted the rudiments of another pair, or a claw broken off on each fide, at the fecond joint or elbow: on thefe extremities are the eyes, like thofe of the horns of fnails, but under the covert of a thick and opaque fhell, nature in that place hath wonderfully contrived a tranfparent lanthorn, through which the light is conveyed.

CYCLOPS. Shell convex, with three lines of raifed fpines; tail very long, and unarmed. It is about one-third the fize of the polyphemus, and is found in India. Shell lunate before, with three raifed dorfal lines, and two acute teeth, finely ferrate behind, with a raifed line in the middle, in which are three teeth.

* APUS. Shell oblong, truncate, and ferrate behind; tail ending in two briftles. It is found in ftagnant water. This is the largeft of the European monoculi. It is a rare fpecies in this country, having been only obferved in a few particular fituations. In its general fhape it is confiderably allied

allied to the large exotic fpecies above-defcribed, but the form of the body is more lengthened. The branchiæ, or refpiratory organs, are large, and diftributed into numerous imbricated rows on the under part of the body: beneath the front is a pair of jointed trifid arms, extending on each fide to a confiderable diftance; the eyes are placed near each other in front of the fhell; the tail is terminated by a pair of long forks, or fetaceous proceffes; the colour of the whole infect is of a pale greenifh-brown above, and reddifh beneath. An account has been given in the 40th vol. of the Phil. Tranf. that this fpecies has been feen in numbers in a pond at Bexley, in Kent. It is alfo added, that the fame pond, having been perfectly dried, and being fuddenly filled, during a heavy thunder-ftorm, fwarms of the fame animals were again obferved in it within the fpace of forty-eight hours after.

* Piscinus. Shell heart-fhaped and flat; body fhort; tail bifid, and compofed of one thin flap. It is a native of European feas. Found on flounders, cod-fifh, falmon, &c. adhering on the outfide between the fcales, running fwiftly, with its tail elevated, both on the fifh and on the water. Shell pellucid, with yellowifh marks; abdomen very fhort, with a long bifid tail.

Pennigerus. Shell hemifpherical, with a linear future; tail feathered. Inhabits frefh water.

Salmoneus. Shell oblong; tail imbricate, and four-leaved. It is found, as its name denotes, fticking to the falmon, between the fcales.

Infects of divifion H have bivalve fhells, two eyes, and capillary antennæ.

Species.

Brachyurus. Shell globular; tail deflected; four antennæ. It is found in marfhes. The fhell is pellucid, reddifh-brown when young, and green as it grows older, with a white eye on the fore-part, and a black one behind; legs are twenty to twenty-four.

* Sphæricus. Shell globular; tail inflected; two antennæ. This fpecies is found among the duck-weed in ftagnant water. It is a native of Europe, and found frequently in this country. It is very minute; the fhell is reddifh; it has two antennæ; twelve legs; and the tail is furnifhed with a fmall hook at the extremity, and concave beneath; the ovariæ are green.

Quadrangularis. Shell quadrangular, hence its fpecific name; tail inflected; antennæ two; legs in number are from twelve to fixteen, befides numerous fmaller ones; the tail is armed with two minute fpines at the tip.

Lamellatus. Shell ventricofe; tail inflected lamellate; antennæ two. Found in ftagnant water. The fhell is convex; eyes are green; legs capillary; the tail has a broad ferrate lamina beneath, and two fpines at the tip.

Trigonellus. Shell gibbous before; tail inflected, ferrate; four antennæ. Found in ditches. The fhell is ciliate, with a fharp probofcis; antennæ with three briftles at the tip; ovaries black.

Truncatus. Shell ovate, and toothed behind; tail inflected, ferrate; four antennæ. Inhabits ftagnant waters. Shell oblique, ftriated, ciliate before, and ferrate behind; the tail is broadifh, and ending in a claw.

Longirostris. Shell roundifh; tail inflected; fhell prickly on the fore-part. It inhabits rivulets. The probofcis is longer than the head, curved, and fubulate.

Macrourus. Shell oblong; tail ftraight; antennæ four. It is found in lakes. The fhell is pellucid, whitifh; legs eight; nail lanceolate.

Socors. Shell ovate; tail projecting, curved; antennæ two. Found in almoft all kinds of waters. The fhell is pellucid, without ftriæ, teeth, or fringe. It has four legs, and the tail is bicufpidate at the tip.

Monoculus, or *Monophthalmus*, (from μονος, *fingle*, and *oculus*, or οφθαλμος, *an eye*,) a bandage in *Surgery*, formerly much more employed than at prefent. It confifted of a roller, ten or twelve feet in length, and about three inches in breadth. It was firft fixed on the occiput, about a foot of the bandage being left hanging down. It was then carried obliquely round the head, over the forehead, to the occiput again. After being applied thrice round the head in this oblique direction, the remainder of the bandage was expended in more horizontal turns. The end, hanging down behind, was laftly brought over the vertex to the forehead, and the whole was fecured with pins. The chief ufe of the monoculus was to retain dreffings and application on difeafes about the eye. The old furgeons had alfo a double monoculus; but it fcarcely merits defcription, as it is now feldom or never made ufe of.

MONODON, in *Ichthyology*, a genus of fifhes of the order Cete. The generic character is: two teeth in the upper jaw, extending ftraight forwards, long, fpiral; fpiracle on the fore and upper part of the head. Dr. Shaw has altered the generic character, by ufing the fingular, *tooth* projecting, inftead of *two teeth*, becaufe though he admits there are fometimes two teeth, yet as the animal is generally found with one only, and becaufe the generic name *monodon* is derived from that very circumftance, the alteration feems neceffary. According to Gmelin there is but one fpecies, *viz.* the *monoceros*, but Dr. Shaw mentions two fpecies. We fhall defcribe them both:

Species.

Monoceros, or *Narwal*, is a native of the northern feas, where it is fometimes feen of more than twenty feet in length from the mouth to the tail. It is at once diftinguifhable from every other kind of whale, by its very long, horn-like tooth, which is perfectly ftraight, of a white or yellowifh-white colour, fpirally wreathed throughout its whole length, and gradually tapers to a fharp point. It meafures from fix to nine or ten feet in length, and proceeds from a focket on one fide of the upper jaw, having a large cavity at its bafe or root, running through the greater part of the whole length. In young ones, and fometimes in thofe that are full grown, there are two teeth, but in general the narwal is found with a fingle tooth, the focket of the other being clofed, or at moft but obfurely vifible, and now and then the appearance of a fecond tooth in an extremely fmall ftate, or juft beginning to emerge, is perceptible, as if intended by nature to fupply the place of the other, if broken or caft. The head of the narwal is fhort, and convex above, the mouth is fmall; the fpiracle or breathing-hole is duplicated within; the tongue is long; the pectoral fins are fmall. The general form of the animal is rather long than thick in proportion to its fize. The colour, when young, is nearly black, but the belly is lighter. As, however, it advances in age, it becomes marbled, or variegated with black and white on the back and fides, while the belly is nearly white. The fkin is fmooth, and there is a confiderable depth of oil or blubber beneath it. It is chiefly found in the northern parts of Davis's ftraits, and its food is fuppofed to confift of fmall flat fifh, as well as of actiniæ, medufæ, and other marine animals. It is commonly feen in the fmall open or unfrozen fpots towards the coafts of the northern feas. To fuch places the narwals refort in multitudes, for the

the conveniency of breathing, and becaufe they are fure to find, near the fhores, a due fupply of food: they are taken by means of harpoons, and the flefh is eaten by the Greenlanders, raw, boiled, and dried; the inteftines and oil are alfo ufed as a food; the tendons make good thread, and the teeth ferve the purpofe of hunting horns, as well as that of building tents and houfes. A throne made for the Danifh monarchs is faid to be ftill preferved in the caftle of Rofenberg, compofed entirely of narwals' teeth, which were formerly confidered as more valuable than gold.

Spurius. This, if it be a diftinct fpecies of the monodon, has a pinnated back, and two fmall teeth in the upper jaw.

It is defcribed by Fabricius, in his *Fauna Groenlandica*, as a fpecies moft allied to the narwal, but not perhaps, ftrictly fpeaking, of the fame genus; it has no teeth in the mouth, but from the extremity of the upper mandible project two minute, conic, obtufe teeth, a little curved at the tips, weak, and not above an inch long; the body is elongated, cylindric, black. Befides the pectoral fins and horizontal tail, there is alfo a minute dorfal fin. Its flefh and oil are confidered as purgative; it is among the rareft of whales, and inhabits the main ocean, feldom coming to the fhore. It has a fpiracle like other whales. It is very feldom taken alive, but found dead on the fhores.

MONODY, Monodia, compounded of μονος, *folus*, and ωδη, *a fong*, in the *Ancient Poetry*, a kind of mournful fong or ditty, fung by a perfon alone, to utter his grief.

Monody, in *Mufic*, a fong for a fingle voice, in oppofition to what the ancients called chorodies, or mufic executed by a chorus.

MONOECIA, in *Botany*, from μονος, *one*, and οικια, *a houfe*, the 21ft clafs of the artificial fyftem of Linnæus, confifting of fuch plants as have barren, or male, flowers on the fame individual with fertile, or female, ones; whereas in the 22d clafs fuch flowers grow upon diftinct individuals of the fame fpecies. (See Dioecia.) How far thefe claffes are natural or not, we have explained under that article.

The orders of *Monoecia* in Linnæus are eleven, diftinguifhed upon the fame principles as thofe of *Dioecia*. 1. *Monandria* is exemplified by *Aegopricon* and *Zannichellia*, permanently monoecious genera, as having a different ftructure in the acceffory parts of their male and female flowers. 2. *Diandria* is fcarcely tenable, one of its two genera, *Anguria*, having no fuch difference of ftructure, and the other, *Lemna*, having certainly the ftamens and piftil in the fame flower, except by accidental or partial imperfection. 3. *Triandria* contains *Carex*, *Sparganium*, &c., with fome plants of the order of *Tricoccæ*, or *Euphorbiæ*, all properly placed here. 4. *Tetrandria* confifts of the *Littorella*, *Betula*, *Buxus*, *Urtica* and others. 5. *Pentandria* embraces a remarkable tribe, clofely allied, for the moft part, to the Syngenefious, or compound, clafs; but their anthers are feparate, and in fome of them, as *Xanthium* and *Nephelium*, the female flowers have no refemblance to that clafs, nor to their own males. 6. *Hexandria* confifts chiefly of a very few graffes. 7. *Heptandria* depends only on *Guettarda*, much better placed in *Pentandria Monogynia*. (See Guettarda and Matthiola.) 8. *Polyandria*, (having eight or more ftamens,) is beft illuftrated by the important genera *Fagus*, *Quercus*, *Juglans*, &c. whofe male flowers are, in moft cafes, amentaceous. 9. *Monadelphia* has the no lefs important genus *Pinus*, with fome of the *Euphorbiæ*. 10. *Syngenefia* confifts of the Gourd or Cucumber tribe; but it is difficult to account for their being placed here, their anthers being in no manner combined. On the contrary, their filaments are more or lefs united, infomuch that Willdenow removes them to the 9th order, *Monadelphia*. This does not feem correct with refpect to any of the tribe; and in thofe we have examined the filaments are united, more or lefs completely, into three fets, fo as ftrictly to conftitute an order of *Monoecia Polyadelphia*, which fhould take place of this 10th Linnæan order. (See Momordica.) 11. *Gynandria*, compofed of *Andrachne* and *Agyneia*, does not appear to exift in nature at all, thefe genera belonging more properly to the 9th order, *Monadelphia*, where fome of their allies already find a place.

We cannot too often proteft againft the abolition of the monoecious and dioecious claffes, whether we confider them in the light of natural or commodious arrangements, although fome plants may have been improperly referred to them.

MONOEMUGI, or Nimaama, in *Geography*, a kingdom of Africa, having, as it is faid, great extent, and reaching northward to Abyffinia; bounded on the E. by the kingdoms of Mongallo, Mozambique, and other fmall ftates along the coaft of the Indian fea; on the S. by Mocaranga, and on the W. by Congo and Angola; but its real limits have not been afcertained. The fovereign, however, is reprefented as a rich and powerful prince, and has fubdued moft of the furrounding and adjacent kingdoms. To this fovereign belong many rich gold, filver, and copper mines, which enable him to carry on commerce with Abyffinia and other countries, as well as with fome of the eaftern coafters, with whom he is under a neceffity of exchanging the precious metals for Indian and European commodities, as he has no port of his own in either the eaftern or weftern fea. Elephants being numerous fupply vaft quantities of ivory for this trade, and afford to the emperor confiderable profit, as well as benefit to his fubjects. M. de Lifle, in his Atlas, divides this kingdom into the five following provinces or fovereignties: *viz.* the Maracates, the Moffagueras, the kingdom of the Bengas, of Mafty, and of Maravi; and this laft M. d'Anville places on the fouthernmoft border of the lake of that name.

MONOGAMIA, in *Botany*, from μονος and γαμος, *a fimple marriage*, the fixth order of the clafs *Syngenefia* in the Linnæan fyftem, as left by its author, deftined to admit fuch genera as have their anthers combined, the flowers being fimple. Such were fuppofed to be *Lobelia*, *Viola*, *Impatiens*, *Jafione*, among Britifh plants, and the exotic *Seriphium*, *Strumpfia*, and *Corymbium*, to which might be added *Calicera*, Cavan. Ic. t. 358, and *Barreria* of Schreber. But the union of the anthers is found by no means univerfal throughout all the fpecies of thefe genera, at leaft of the two firft, which are very natural genera; and on the other hand this union occurs here and there among the fpecies of others no lefs natural, as *Gentiana*. In fhort, the character in queftion proves of no avail in fimple flowers; nor is there any natural affinity, between the above Britifh genera at leaft, and the moft natural clafs of compound flowers with combined anthers, the true *Syngenefia*. *Seriphium* and *Corymbium* caufe no difficulty; for they are in every refpect genuine Syngenefious plants, and though the florets are folitary in each partial calyx, the flowers are aggregate, or collected in a common calyx; fo that they readily go to the 5th order of *Syngenefia*, termed *Polygamia-fegregata*, and ferve but to ftrengthen and confirm that moft natural clafs. The order *Monogamia* is now therefore generally abolifhed, certainly with great advantage. The plants which compofed it are removed to *Pentandria Monogynia*, where moft of them meet with many natural allies. *Calicera* of Cavanilles appears to be referrible to *Syngenefia Polygamia-fegregata*. The affinity of *Strumpfia* is doubtful. *Barreria*, Aublet's *Poraqueiba*, is confidered by Juffieu as akin to his *Berberides*.

MONO-

MONOGAMY, compounded of μονος, *ſolus*, and γαμος, *marriage*, the ſtate or condition of thoſe who have only married once, or are reſtrained to a ſingle wife. See POLYGAMY.

MONOGASTRIC, in *Anatomy*, a name given by Vieuſſens, and ſome of the French writers, to one of the muſcles of the ear, called by Cowper the internus auris, and more properly by Albinus, the tenſor tympani.

MONOGRAM, MONOGRAMMUS, a cipher, or character, compoſed of one or more letters interwoven; being a kind of abbreviation of a name; anciently much uſed as a badge, ſeal, arms, &c.

Among medalliſts, a monogram is the name of a prince, city, or the like, of which the characters are, as it were, woven together, and the limb of one character applies to three or four others; ſo that in the ſmall ſpace of one or two characters a whole name is comprehended.

Under the eaſtern empire, it is uſual to find M I K, which are the monogram of Maria, Jeſus, Conſtantine.

The uſe of monograms is of an ancient ſtanding, as appears from Plutarch, and from ſome Greek medals of the time of Philip of Macedon, Alexander his ſon, &c. The Roman labarum bore the monogram of Jeſus Chriſt, conſiſting of two letters, a P placed perpendicularly through the middle of an X, *e. gr.* ☧, as we find it in ſeveral medals of the time of Conſtantine, thoſe being the two firſt letters of the word Χριστος, *Chriſt*.

Kings formerly marked their coins with their monograms: of this we have inſtances in Charlemagne's coins. That prince alſo uſed the monogram for his ſignature. Eginhard gives us this reaſon for it, *viz.* that Charlemagne could not write; and that, having attempted in vain to learn in his grown age, he was reduced to the neceſſity of ſigning with a monogram.

The ancients alſo uſed monograms as notes, or abbreviations of inſcriptions; for the underſtanding of which we have expreſs treatiſes of Valerius Probus, Sert. Urſatus, &c.

MONOGRAPHI, in *Botany*, authors who have written expreſs treatiſes on only one plant; as Douglas on the Guernſey lily, &c.

MONOGYNIA, from μονος, *one*, and γυνη, *a female*, is the name of ſuch orders in the firſt thirteen claſſes of the Linnæan ſyſtem, as have a ſingle ſtyle, or ſeſſile ſtigma, in each flower. A ſingle ſtyle however is by no means confined to theſe claſſes, being univerſal in the 14th and 15th as well as in the 17th and 19th, all very extenſive and natural claſſes of the ſame ſyſtem, and it occurs here and there amongſt the others; though in none of theſe inſtances does it give a denomination to any order, or ſection. See DIGYNIA.

MONOK, in *Geography*, a town of Hungary; 12 miles W.N.W. of Tokay.

MONOKA, a river of Maryland, which runs into the Cheſapeak, N. lat. 38° 10'. W. long. 76° 53'.

MONOLOGUE, Fr. an opera tune by one actor alone, who only ſpeaks or rather ſings to himſelf. In declamation it is a ſoliloque. "It is in monologues (ſay the French) that all the powers of muſic are diſplayed; the performer giving way to all the ardour of his genius, unreſtrained in the length of his air or recitative by the preſence of an interlocutor." The accompanied recitatives of the Italians, which produce ſuch great effects, are always monologues.

MONOMACHIA, Μονομαχια, from μονος, *ſolus*, and μαχη, *combat*, a duel, or ſingle combat of man againſt man. Monomachia was anciently allowed by law, for the trial or proof of crimes. It was even permitted in pecuniary cauſes, as appears by ancient records. It is now forbidden both by the civil and canon laws. See COMBAT.

Alciat has written a treatiſe "De Monomachiâ."

MONOMERES, a word uſed by the ancients alone, but more frequently joined with the word *phorbeia*, to expreſs one ſort of the bandage uſed to confine the breath, by thoſe who played on the ancient pipe. This conſiſted only of one ſtraight and one tranſverſe piece; and the latter came fully over the mouth, and cloſed it up, except that a hole was cut in it to receive the mouth-piece of the pipe. The *diemeres* conſiſted of ſeveral pieces, and only tied up the lower-lip.

MONOMIAL, in *Algebra*, a root or quantity that has but one name; or conſiſts but of one part or member. Such are *a b*, *a a b*, *a a a b b*. See QUANTITY, BINOMIAL, TRINOMIAL, ROOT, &c.

Monomials may be either rational, or irrational.

MONOMIES CASTLE, in *Geography*, a fort of America, on the river Winebago. N. lat. 44° 18'. W. long. 87° 34'.

MONOMIES *River*, a river of North America, from which is derived the name of a tribe of Indians, and which runs into that part of lake Michigan, called "Green bay," N. lat. 44° 46'. W. long 87° 27'.

MONOMONIL, a town of N. America, on the W. ſide of Green bay. N. lat. 44° 32'. W. long. 87° 28'.

MONOMOTAPA. See MOCARANGA.

MONONGAHELA RIVER, a branch of the Ohio, 400 yards wide at its junction with the Alleghany at Pittſburg; navigable with batteaux and barges beyond Redſtone creek, and ſtill farther with lighter craft. It riſes at the foot of the Laurel mountain in Virginia, paſſes into Pennſylvania, ſeparates Fayette and Weſtmoreland from Waſhington county, and then joining the Alleghany river at Pittſburg, forms the Ohio.

MONONGALIA, a county in the N.W. part of Virginia, about 40 miles long and 30 broad; containing 8540 inhabitants.

MONOPAGIA, a word uſed by ſome *medical* writers, for that ſpecies of head-ache which affects only one point, or ſmall part of the head.

MONOPETALOUS, in *Botany*, a flower whoſe *corolla* conſiſts of but one piece, or petal, as in the Primroſe. A monopetalous corolla is almoſt univerſally tubular. Very rarely the tube is ſlit, from top to bottom, at one ſide, as in *Goodenia* and *Scævola*. There are indeed a few monopetalous flowers which ſeem to be ſo from a partial defect, as *Amorpha*, the only petal of whoſe corolla is the ſtandard (*vexillum*), the wings and keel being wanting, though the form of every part of the fructification, as well as the habit of the ſhrub, indicates its ſtrictly papilionaceous nature. Another genus, *Rittera* of Schreber, (*Poſſira* of Aublet and Juſſieu,) which is alſo of the leguminous kind, though not papilionaceous, has a ſingle lateral petal, of a broad roundiſh figure, with a very ſhort claw. (See RITTERA.) The diſtinction between a monopetalous and polypetalous corolla, is the moſt abſolute of all, in the ſyſtems of thoſe who arrange plants by this part; and is indeed leſs liable to variation than even the abſence or preſence of the corolla itſelf. See COROLLA and CLASSIFICATION.

MONOPHAGI, Μονοφαγοι, in *Antiquity*, a deſignation given to thoſe who celebrated the Æginean feſtival, becauſe they feaſted or eat together without the aſſiſtance of their ſervants; none but the denizens of that iſland being allowed to be preſent.

MONOPHYSITES, from μονος, *solus*, and φυσις, *natura*, in *Ecclesiastical History*, a general name given to all those sectaries in the Levant, who only own one nature in Jesus Christ; and maintain, that the divine and human natures of Christ were so united, as to form only one nature, yet without any change, confusion, or mixture of the two natures. See EUTYCHIANS.

The Monophysites, however, properly so called, are the followers of Severus, a learned monk of Palestine, who was created patriarch of Antioch in 513, and Petrus Fullensis, whence they were called " Severians."

The Monophysites were encouraged by the emperor Anastasius, but depressed by Justin and succeeding emperors. However, this sect was restored by the eloquence, activity, and diligence of Jacob Baradæus, an obscure monk, insomuch, that when he died bishop of Edessa, A.D. 578, he left it in a most flourishing state in Syria, Mesopotamia, Armenia, Egypt, Nubia, Abyssinia, and other countries. The laborious efforts of Jacob were seconded in Egypt, and the adjacent countries, by Theodosius, bishop of Alexandria, and he became so famous, that all the Monophysites of the East considered him as their second parent and founder, and are to this day called Jacobites, in honour of their new chief. The Monophysites are divided into two sects or parties; the one African, the other Asiatic: at the head of the latter is the patriarch of Antioch, who resides, for the most part, in the monastery of St. Ananias, near the city of Merdin, his episcopal seat; and also at Amida, Aleppo, and other Syrian cities: the former are under the jurisdiction of the patriarch of Alexandria, who generally resides at Grand Cairo, and are subdivided into Cophts and Abyssinians. From the fifteenth century downwards, all the patriarchs of the Monophysites have taken the name of Ignatius, in order to shew that they are the lineal successors of Ignatius, who was bishop of Antioch in the first century, and consequently the lawful patriarchs of Antioch. In the 17th century, a small body of the Monophysites in Asia, abandoned, for some time, the doctrines and institutions of their ancestors, and embraced the communion of Rome: but the African Monophysites, notwithstanding that poverty and ignorance which exposed them to the seductions of sophistry and gain, stood firm in their principles, and made an obstinate resistance to the promises, presents, and attempts employed by the papal missionaries, to bring them under the Roman yoke: and in the 18th century, those of Asia and Africa have persisted in their refusal to enter into the communion of the Roman church, notwithstanding the earnest intreaties and alluring offers, that have been made from time to time by the pope's legates, to conquer their inflexible constancy. The Monophysites propagate their doctrine in Asia with zeal and assiduity, and have not long ago gained over to their communion a part of the Nestorians, who inhabit the maritime coasts of India. Mosheim's Eccl. Hist.

MONOPIN HILL, in *Geography*, a hill on the island of Banca, which forms the N.E. point of the entrance of the Straits. S. lat. 2° 3′. E. long. 105° 18′. The difference of longitude between the island Lusepara, which lies in the S. entrance of the straits of Banca, and Monopin hill, which forms one side of the entrance from the north, is 55′. See *Straits of* BANCA.

MONOPOLI, a town of Naples, in the province of Bari, on the coast of the Adriatic sea; the see of a bishop; containing six churches and nine convents; 144 miles E. of Naples. N. lat. 41° 8′. E. long. 17° 19′.

MONOPOLY, strictly speaking, in the language of the law, is very similar to engrossing: the latter is the act of buying up corn and other provisions, for the purpose of selling them again; the former is the same offence, extended to other branches of trade: both are supposed to be done for the purpose of gaining the entire command of the market, and by this means raising the prices of the commodities engrossed or monopolised.

Monopoly is also a term applied to a " licence or privilege allowed by the king, for the sole buying, selling, making, working and using of any thing whatsoever, whereby the subject is restrained from that liberty of manufacturing or trading which he had before." These licences and privileges, in all despotic governments, have been made use of to favour and enrich individuals; or, by the sale of them, to contribute to the wants of the sovereigns: and even in freer governments, ignorant of the real mode of promoting industry and enriching the people, licences and privileges of this kind have been too frequently granted on the erroneous idea, that their commerce would be fostered and protected in its infancy. In this kingdom, during the reigns of Elizabeth and James I. monopolies were carried to a most vexatious and destructive extent; so that many branches of trade and manufacture were absolutely closed, except to those who had obtained licences to engage in them, and the great body of consumers were inadequately supplied with bad articles at an exorbitant rate. These evils at last became so oppressive and glaring, that by the 21st James I. c. 3. all such monopolies were declared to be contrary to law and void (except patents to the authors of new and useful inventions, for a term not exceeding fourteen years). By the same statutes, monopolists are liable to be punished by treble damages and double costs, if they disturb any persons engaged in a trade to which they claim the privilege of monopoly. This statute evidently refers only to those cases where a monopoly licence is claimed, and endeavoured to be acted upon, so as to disturb the trade of those engaged in the same line.

The engrossing or monopoly of corn and provisions is an offence at common law, and is described by statute 5 and 6 Edw. VI. c. 14.; by this statute, the penalty is the forfeiture of the goods or their value, and two months imprisonment for the first offence; double value, and six months imprisonment for the second; and for the third, the offender to forfeit all his goods, to be set in the pillory, and imprisoned at the king's pleasure.

Monopoly, as a subject in political economy, may be considered under three points of view. In the first place, the practicability of the alleged crime of getting into one's possession, or buying up, all, or such a quantity of, any commodity as will give the command of the market, and consequently of the price. In the second place, the monopoly, which by patent is given for a term of years, to the authors of new and useful inventions: the propriety and policy of this kind of monopoly afford ample room for discussion; of course, if this kind of monopoly were to be set aside, some other mode of rewarding the authors of new inventions, less objectionable, must be suggested: this kind of monopoly will be considered under the article PATENT. In the third place, that species of monopoly, wherein a government grants either to a body of men, which secures them any particular trade; or to the nation at large, by which the colonial trade is not suffered to be touched by any foreign nation. This last species of monopoly, or the monopoly of the colonial trade, will be considered under the article NAVIGATION *Act*: at present, therefore, we shall confine our observations to the alleged crime of engrossing or monopolizing any commodity, for the purpose of commanding the market, and raising the price; and to that monopoly which

which a government grants to any particular body of men, by which they alone can carry on the trade which is the object of the monopoly.

Smith's opinion reſpecting engroſſing and foreſtalling is well known: the popular fear reſpecting them he compares to the popular terrors and ſuſpicions of witchcraft, and he concludes by obſerving, that the law which ſhould reſtore entire freedom to the inland trade of corn would probably prove as effectual to put an end to the popular fears of engroſſing and foreſtalling; as the law which put an end to all proſecutions for witchcraft, deſtroyed the fear and ſuſpicion of it, by taking away the great cauſe which encouraged and ſupported them.

Indeed, when we conſider the numerous and great obſtacles and difficulties which muſt lie in the way of every perſon who attempts to get into his poſſeſſion the whole, or the greater part of any commodity; the immenſe capital, or credit which he muſt poſſeſs; the confidence he muſt place on the integrity of his agents, and the reliance he muſt have on their ſkill and judgment; the effect on the price of the commodity, which his attempts to monopolize it muſt neceſſarily produce; and the great probability that he will be compelled to deſiſt from his undertaking, long before he has brought it to a cloſe, from an erroneous calculation of his means: it will appear evident that it cannot be the intereſt of any man to riſque his capital in ſuch an abſurd and impracticable undertaking. If there ſhould be perſons ſo blind to their own intereſts as to begin the attempt, their puniſhment may ſafely be left to flow from their own meaſures, as, long before they can materially, or even in a trifling degree, injure the public, they will either open their eyes to their own folly, or be incapacitated by their own ruin from proceeding in their enterpriſe.

But though monopoly, ſtrictly ſpeaking, appears thus impracticable, yet there is no doubt that the price of commodities may be partially and temporarily affected by the quantity of capital poſſeſſed by thoſe who have them for ſale. It is well known that if the farmer, for inſtance, be ſtraightened for money, he will be compelled to bring his grain to market early in the ſeaſon, in a much larger proportion than if his capital were ſufficient to enable him to pay his rent, and carry on his agricultural labour, without having recourſe to this meaſure: if, on the other hand, his capital is ſuch, that he has no occaſion for the money the early ſale of his corn would produce, he will bring it to market only in thoſe quantitities, and at thoſe ſeaſons, which he thinks will conduce moſt to his own intereſt. At firſt ſight it might ſeem as if the public would be moſt benefited by farmers of the former deſcription; but a very little reflection will convince us, that the temporary reduction in the price of corn, occaſioned by their want of adequate capital, will be much more than balanced, in a national point of view, by the unequal diſtribution of it through the year, to which this will give riſe, as well as by the want of economy in the uſe of it, which the forced and unauthorized reduction of it will produce.

It may then ſafely be inferred that the attempt to monopolize any commodity is ſo abſurd, and ſo contrary to the moſt narrow and obſcure views of ſelf-intereſt, that no law is neceſſary to prevent or puniſh it; and that, with reſpect to the ſuppoſed effect of capital, in raiſing the price of commodities, in many points of view capital, by enlarging the quantity produced, and giving riſe to competition, muſt have the oppoſite effect; while an inadequate capital muſt narrow and thwart the induſtry and operations of the poſſeſſor, and even at the time that it compels him to diſpoſe of his produce, is injurious, not only to himſelf, but to the nation at large.

In a monopoly of the colony trade, no particular body of men in the nation are favoured: the monopoly regards the whole nation as contradiſtinguiſhed from foreigners: but in the monopoly of any trade granted by government to a particular body of men, the privilege is granted at the expence, and to the loſs of the reſt of the nation. This is the firſt and moſt ſtriking evil, but there are others not inferior in magnitude and extent. Not only is a large portion of the nation excluded from the means of increaſing their induſtry and conſequently their wealth; but they are compelled to purchaſe the articles of the monopoly trade at the monopoly price, and to ſell ſuch articles as they manufacture for that trade, at the price which the holders of the excluſive privilege may chooſe to give. Nothing ſupplies a market ſo regularly, or ſo cheaply, or with goods of ſuch good quality, as open and fair competition; nothing, on the contrary, renders the ſupply ſo irregular, or the goods ſo high priced, or of ſuch inferior quality, as monopoly. For theſe and various other ſubordinate reaſons, therefore, a monopoly trade muſt be injurious to the nation at large; and it not unfrequently happens that it is conducted with ſuch negligence, ignorance, and extravagance, as not to be beneficial to thoſe who poſſeſs it. Under certain circumſtances, when there was little ſpirit of enterprize, when individual capital was ſmall, and combined with theſe circumſtances, in caſes where the riſque was great, where great length of time was neceſſary to eſtabliſh the trade, and where the returns, at firſt, were ſlow and trifling, it might have been wiſe and politic to grant excluſive privileges of trade; but certainly it cannot be wiſe and politic to grant or to continue them, under circumſtances of an oppoſite deſcription.

MONOPS, in *Natural Hiſtory*, a name given by Ælian, and ſome other of the old Greek writers, to the bonaſus. The name *monapus* was given this animal, according to Ariſtotle, by the people of the country where the creature was moſt frequent, and therefore is not to be attempted on any Greek etymology. Some of the Greeks have called the ſame creature *monepos*, and ſome *bolinthos*.

MONOPTERE, Μονόπτερος, a kind of temple among the ancients, round, and without walls; having its dome ſupported by columns.

MONOPTOTE, Monoptoton, in *Grammar*, a noun, which has only one caſe; as *inficias*.

MONOPTRAL Temple, in *Architecture*, an edifice, conſiſting of a circular colonnade ſupporting a dome. The monoptral temple is open, or without any incloſing wall, and conſequently without a cell, as in other temples.

MONOPYRENEOUS Fruits, in *Botany*, are ſuch as only contain one kernel or ſeed.

MONORCHIS, the ſpecific name of an *Ophrys* in Linnæus, Sm. Fl. Brit. 936. Engl. Bot. t 71, which remains in the ſame genus in Dr. Swartz's new arrangement of this tribe. It is ſo called from having but one apparent globular bulb, or rather knob, to the root; the other being formed at the end of a longiſh ſhoot, about, or after, the time of flowering, ſo as commonly to eſcape obſervation.

Monorchis. Beſide the common ſignification of this word as the name of a plant, phyſicians have alſo uſed it to expreſs a man who has but one teſticle.

MONORHYMÆ, from μονος, *ſolus*, and ρυθμος, *rhyme*, a poetical compoſition, all the verſes of which end with the ſame rhyme.

Monorhymes are ſaid to have been invented by the old French poet Leonin, who addreſſed ſome Latin verſes of

this

this kind to pope Alexander III., whence they are alſo called Leonine verſes.

MONOS, in *Geography*, a river of Guinea, which runs into the Atlantic, 15 miles S. of Tombi.

MONOSPERM-ALTHÆA, in *Botany*, a name contrived by Iſnard for the *Waltheria* of Linnæus, and intended to expreſs a plant of the Marſh-mallow kind, with a ſingle ſeed. See WALTHERIA.

MONOSTICH, MONOSTICHON, an epigram, or poetical piece, conſiſting of one ſingle verſe.

MONOSYLLABLE, MONOSYLLABUM, a word of a ſingle ſyllable; or, that conſiſts of one or more letters which are pronounced together.

The French language abounds in monoſyllables more than any other. This renders it the more perplexing to foreigners, and yet the beauty of the language ſeems to conſiſt in it. One of the beſt and ſmootheſt lines in Malherbe conſiſts of twelve monoſyllables: ſpeaking of Caliſta, he ſays, "Et moi je ne voi rien quand je ne la voi pas." In this the genius of the Engliſh tongue differs very much from the French, an uninterrupted ſeries of monoſyllables in the former having always an ill effect. This Mr. Pope both intimates and exemplifies in the ſame verſe. "And ten low words oft creep in one dull line." Paſquier cites an elegy of forty-two verſes, conſiſting wholly of monoſyllables.

MONOTHELITES, compounded of μονος, *ſingle*, and θελημα, *will*, of θελω, *volo*, *I will*, in *Eccleſiaſtical Hiſtory*, an ancient ſect, which ſprung out of the Eutychians and Monophyſites; thus called, as only allowing of one will in Jeſus Chriſt.

The opinion of the Monothelites had its riſe in 630, and had the emperor Heraclius for an adherent, who, by publiſhing an edict in favour of it, hoped thus to reſtore peace and concord both in church and ſtate: it was the ſame with that of the Acephalous Severians.

They allowed of two wills in Chriſt, conſidered with regard to the two natures; but reduced them to one, by reaſon of the union of the two natures; thinking it abſurd there ſhould be two free wills in one and the ſame perſon. See ECHTHESIS and TYPE.

They were condemned by the ſixth general council, in 680, as being ſuppoſed to deſtroy the perfection of the humanity of Jeſus Chriſt, depriving it of will and operation. Moſheim gives the following account of the ſtate of this ſubtile controverſy; the grounds of which are not, indeed, eaſily underſtood and explained. 1. The Monothelites declared, that they had no connection with the Eutychians and Monophyſites; but maintained, in oppoſition to both theſe ſects, that in Chriſt there were two diſtinct natures, which were ſo united, though without the leaſt mixture or confuſion, as to form by their union only one perſon. 2. They acknowledged, that the ſoul of Chriſt was endowed with a will, or faculty of volition, which is ſtill retained, after its union with the divine nature. For they taught, that Chriſt was not only perfect God, but alſo perfect man; whence it followed, that his ſoul was endowed with the faculty of volition. 3. They denied that this faculty of volition in the ſoul of Chriſt was abſolutely inactive; maintaining, on the contrary, that it co-operated with the divine will. 4. They, therefore, in effect, attributed to our Lord two wills, and theſe, moreover, operating and active. 5. They, however, affirmed, that, in a certain ſenſe, only one will and one manner of operation were in Chriſt. Their ſentiments were afterwards embraced by the Maronites.

MONOTOCA, in *Botany*, from μονος, *one*, and τοκος, *a fœtus*, or *conception*, becauſe the germen has, from the firſt, the rudiments of but one ſeed, by which this genus is diſtinguiſhed from others of its natural order. Brown. Prodr. Nov. Holl. v. 1. 546.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Epacrideæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of five equal, erect, concave, permanent leaves, with a pair of ſmaller ones at the baſe, which are ſometimes deciduous. *Cor.* of one petal, funnel-ſhaped, twice the length of the calyx; its limb in five equal, ſpreading, ſmooth, beaked ſegments; throat naked and pervious. Nectary a lobed cup-ſhaped gland, ſurrounding the baſe of the germen. *Stam.* Filaments five, thread-ſhaped, equal, inſerted into the tube of the corolla, ſhorter than its limb; anthers oblong, incumbent. *Piſt.* Germen ſuperior, roundiſh; ſtyle columnar, ſhort; ſtigma obtuſe. *Peric.* Drupa oval, pulpy. *Nut* ſolitary, oval, of one cell. *Seed* ſolitary.

Eſſ. Ch. Outer calyx of two leaves. Corolla five-cleft, funnel-ſhaped, naked at the mouth and border. Germen ſingle-ſeeded. Drupa pulpy.

A New Holland genus of ſhrubs, or ſmall trees, ſeparated by Mr. Brown from the *Styphelia* of preceding authors, on account of the above characters. The *leaves* are ſcattered, ſimple. *Spikes* axillary, rarely terminal, of few *flowers*, which are ſmall, white, often becoming dioecious, by a partial defect in their organs of impregnation.

Section 1. *Outer calyx deciduous. Small trees, with dioecious flowers.*

1. M. *elliptica.* (Styphelia elliptica; Sm. Bot. of New Holl. 49.)—Cluſters erect, either nearly terminal and aggregate, or axillary and ſolitary. Leaves elliptic-oblong, four times as long as broad.—Sent by Dr. J. White, in 1793, from the neighbourhood of Port Jackſon, New South Wales, where it was alſo gathered by Mr. Brown. The *branches* are variouſly divided, round, leafy, downy when young. *Leaves* numerous, ſcarcely an inch long, obovate or elliptic-lanceolate, entire, tipped with a ſpinous point; dark glaucous green and ſmooth above; pale, convex, with ſomewhat radiating, but nearly parallel, ribs beneath. *Footſtalks* broad and ſhort. *Cluſters* about the length of the leaves, their ſtalks angular and downy. *Bracteas* ſolitary, concave, at the baſe of each partial ſtalk. *Flowers* ſcarcely a line in length. The outer calyx is permanent in our ſpecimens.

2. M. *albens.* Br. n. 2.—Cluſters erect, ſolitary, either terminal or axillary. Leaves oblong-linear, acute, ſpinous-pointed, white beneath.—Native of Port Jackſon. Like the former, but the *leaves* are longer, narrower, and paler, more tapering at the point, their edges appearing minutely crenate under a microſcope.

3. M. *lineata.* Br. n. 3. (Styphelia glauca; Labill. Nov. Holl. v. 1. 45. t. 61.)—Spikes axillary, very ſhort, drooping, ſtalked. Leaves elliptic-oblong, acute, ſpinous-pointed, nearly flat.—Native of Van Diemen's land, where it was gathered by both the above authors. The ſhape of the *leaves* is moſt like the firſt ſpecies, but the very ſhort, axillary, ſtalked, obtuſe *ſpikes* (not *cluſters*), which Mr. Brown ſays are drooping, though the French author repreſents them erect, diſtinguiſh the preſent plant. The *germen* is, erroneouſly it ſeems, drawn with five cells in Labillardiere's plate.

Section 2. *Outer calyx permanent. Shrubs, with both organs of the flower perfect.*

4. M. *ſcoparia.* (Styphelia ſcoparia; Sm. Bot. of New Holl. 48.)—Spikes axillary, very ſhort, nearly ſeſſile, drooping, of few flowers. Leaves linear-oblong, ſomewhat revolute.

revolute. Stem erect.—Native of Port Jackſon, New South Wales. The *ſtem* is very buſhy, branched in a determinate manner, ſmooth throughout. *Leaves* numerous, about half an inch long, narrow, but ſomewhat elliptical, entire, ſpinous-tipped, the edges reflexed. *Flowers* ſmall, three or four, in a little, recurved, minutely bracteated, ſpike.

5. M. *empetrifolia.* Br. n. 5.—"Spikes axillary, drooping, of two or three flowers. Leaves oblong-oval, pointed, divaricated; convex above; ſtriated and whitiſh beneath. Stem proſtrate."—Gathered by Mr. Brown in Van Diemen's land. Of this we have ſeen no ſpecimen.

MONOTONIA, Monotony, in *Rhetoric*, a want of variation, or inflexion of the voice; or a fault in pronunciation, where a long ſeries of words is delivered with one unvaried tone. This is one of the principal faults of our Engliſh orators.

Dr. Blair obſerves, that monotony is the great fault into which writers are apt to fall, who are fond of harmonious arrangement; and to have only one tune, or meaſure, is not much better than having none at all. A very vulgar ear will enable a writer to catch ſome one melody, and to form the run of his ſentences according to it; which ſoon proves diſguſting. But a juſt and correct ear is requiſite for varying and diverſifying the melody; and hence we ſo ſeldom meet with authors, who are remarkably happy in this reſpect.

In pronunciation, care ſhould be taken to guard againſt monotony. It is juſtly obſerved by a good writer on this ſubject, that for an orator always to uſe the ſame tone or degree of his voice, and to expect to anſwer all his views by it, would be much the ſame thing, as if a phyſician ſhould propoſe to cure all diſtempers by one medicine. From hence it is evident, that though various inflections and tones of the voice are requiſite to make it harmonious and pleaſing to the ear, yet the degree of it ſhould differ according to the nature of the ſubject, and deſign of the ſpeaker. And as a perfect monotony is always unpleaſant, ſo it can never be neceſſary in any diſcourſe. Lect. on Rhet., &c. vol. i. Ward's Orat., vol. ii. See Period, Pronunciation, Sentence, and Voice.

Monotonia is oppoſed to chanting or ſinging in ſpeaking.

MONOTONOUS, Monotony, uſed figuratively in muſic, except in ſpeaking of drums, implies dull, pſalmodic ſtrains, always in the ſame ſtyle or key.

MONOTRIGLYPH, in *Architecture*, denotes the ſpace of one triglyph, between two pilaſters or two columns.

MONOTROPA, in *Botany*, received that appellation from Linnæus, in exchange for *Hypopitys*, though the alteration ſeems, in our humble opinion, by no means for the better. The word is formed from μονος, *one*, and τρεπω, *to regard* or *conſider*, alluding to the regard paid by its author to the ſingle terminal flower, for the determination of the claſs and genus, in preference to the lateral ones, according to a favourite principle aſſumed by himſelf, and exemplified in this genus, *Ruta*, *Adoxa*, *Chryſoſplenium*, and others. He appears in the *Philoſophia Botanica*, p. 186, to have loſt ſight of this original idea, claſſing the name in queſtion with thoſe deduced from the ſoil, ſtumbling, as it were, between *ſolum* and *ſolus;* an error rather to be lamented than cenſured, when we reflect that this immortal book was dictated haſtily from a ſick bed. (See Linnæus.) We muſt nevertheleſs ſtill contend, that the name previouſly beſtowed on this plant by Bauhin and Dillenius, from ὑπο, *under*, and πιτυς, *a fir-tree*, alluding to its perhaps invariable ſtation, was liable to no exception. Linn. Gen. 214. Schreb. 291. Willd. Sp. Pl. v. 2. 573. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 440. Juſſ. 430. Michaux Boreali-Amer. v. 1. 266. (Hypopitys; Dill. Gen. 134. t. 7.)—Claſs and order, *Decandria Monogynia.* Nat. Ord. doubtful, Linn. Juſſ. The latter obſerves, that it is "a genus by itſelf, akin to no other." Its habit is that of *Cytinus*, whatever difficulty there may be in bringing them together by technical characters. The want of green in the colour of ſuch paraſitical plants is remarked by Linnæus, in Fl. Suec. 135, though the diſcovery has lately been attributed to one of his pupils.

Gen. Ch. *Cal.* none, unleſs the five outer petals be conſidered as a coloured calyx. *Cor.* Petals ten, inferior, oblong, erect, parallel, ſerrated at the extremity, deciduous; the five outermoſt, or alternate, ones gibbous at the baſe, concave, and bearing honey, at the inſide. *Stam.* Filaments ten, awl-ſhaped, erect, ſimple; anthers ſimple, two-lobed. *Piſt.* Germen ſuperior, roundiſh, pointed; ſtyle cylindrical, the length of the ſtamens; ſtigma capitate, obtuſe. *Peric.* Capſule ovate, with five angles, obtuſe, of five valves. *Seeds* numerous, chaffy.

Obſ. This deſcription is taken from the terminal flower, according to the rule in *Phil. Bot.* ſect. 178. The lateral flowers, in ſuch ſpecies as have any, loſe one-fifth, in the number of every part of the fructification.

Eſſ. Ch. Calyx none. Petals ten; the five outermoſt concave and honey-bearing at their baſe. Capſule ſuperior, of five valves.

1. M. *Hypopitys.* Yellow Bird's-neſt. Linn. Sp. Pl. 555. Engl. Bot. t. 69. Fl. Dan. t. 232. Ehrh Phytoph. 44. (Orobanche hypopitys lutea; Mentz. Pugill. t. 3. Moriſ. ſect. 12. t. 16. f. 13.)—Flowers ſpiked, externally ſmooth, as well as their bracteas; the lateral ones octandrous.—Native of fir woods in Europe and North America, growing paraſitically on the roots of thoſe trees, and flowering in July. Dillenius ſays, on the authority of Mr. Manningham, that it grows alſo in beech woods. Michaux aſſerts the American plant to be but half the ſize of the European. With us it is nearly a ſpan high. The whole herb ſucculent, of a pale ſtraw-colour, turning browniſh when arrived at maturity, and then acquiring a fragrant ſmell, like that of primroſe flowers, though generally compared to their roots. The *ſtem* is ſimple, thick, round, clothed with ſcattered ovate *ſcales*, rather than *leaves*, and terminating in a *ſpike* of ſeveral *flowers*, at firſt drooping, finally erect. Each *flower* is accompanied by a *bractea*, exactly reſembling the ſcales of the ſtem, rather ſhorter than the *flower*, which, with its very ſhort partial ſtalk, is nearly an inch long. Sometimes the *ſtamens*, and inner ſide of the *petals*, are hairy. Willdenow ſays there is a variety with upright flowers, which is occaſionally ſingle-flowered. We have ſometimes found the lateral bloſſoms with only ſix petals and ſtamens.

2. M. *lanuginoſa.* Downy Bird's-neſt. Michaux n. 2.—Flowers ſpiked, all over downy, as well as their bracteas.—Sent from North America, by Kalm, to Linnæus, who confounded it with the former. Michaux gathered the ſame in the woods of North Carolina. He juſtly deſcribes it as having the habit of the foregoing, but ſmaller in all its parts, varying with a drooping or upright *ſpike*, the *flowers* turned all one way. The *ſcales* of the *ſtem* are rather pointed. The *ſtem*, *ſcales*, *petals*, and every other part of the *flowers*, are clothed with fine, ſoft, denſe hairs, peculiar to this ſpecies. The ſpecimen of the former in the Linnæan herbarium, as well as one we have from France, has indeed ſcattered hairs on the *ſtamens*, as well as on the inner ſide of the *petals*, near the edge. Whether theſe indicate a ſpecific diſtinction,

diſtinction, we have not materials to decide, but we have ſeen them in no Britiſh ſpecimen.

3. M. *uniflora*. Drooping Single-flowered Bird's-neſt. Linn. Sp. Pl. 555. Michaux n. 3. (Orobanche virginiana, flore pentapetalo cernuo; Pluk. Phyt. t. 209. f. 7.) — Stem ſingle-flowered. Scales bluntiſh. Flower pendulous.—Native of Maryland, Virginia, and Canada; *Linn.*; of ſhady woods in South Carolina; *Michaux*. *Root* a denſe congeries of entangled fibres. *Stem* about ſix inches high, ſeldom quite ſtraight in any part, angular, ſmooth. *Scales* obovate, bluntiſh, ſmooth, ſcattered, not numerous. *Flower* terminal, ſolitary, perfectly pendulous, the upper part of the ſtem, for about an inch, being curved into an arch. *Corolla* bell-ſhaped, the ſize of the firſt ſpecies, or bigger. *Stamens* ten, hairy. Plukenet's figure is very good.

4. M. *Moriſoniana*. Upright Single-flowered Bird's-neſt. Michaux n. 4. (Orobanche monanthos virginiana, flore majore; Moriſ. ſect. 12. t. 16. f. 5.)—Stem ſingle-flowered, ſtraight. Scales lanceolate. Flower erect.—Native of the ſhady woods of Carolina. *Michaux*. A ſpecimen, ſent by Kalm from North America, is confounded in the Linnæan herbarium with the laſt. The *ſtem* of the preſent ſpecies is nearly twice the height of *M. uniflora*, perfectly ſtraight, except its taper baſe, which is ſlightly flexuoſe. *Scales* larger, more lanceolate and acute, eſpecially the upper ones. *Flower* always perfectly erect, about the ſize of the laſt, or rather bigger, with ten *petals*, and as many hairy *ſtamens*.

Moriſon's figure, with which Linnæus finds fault, ſuppoſing it done for the foregoing, expreſſes this ſpecies ſufficiently well. Michaux has firſt diſtinguiſhed the two, and, as it appears to us, very juſtly. He deſcribes the *ſcales* as more diſtant in the preſent, which is not the caſe in the only ſpecimen we have ſeen, any more than in Moriſon's plate. The *ſtem*, in five ſpecimens of the *uniflora* before us, is alſo the moſt ſlender of the two; Michaux terms it thick, as well as ſhorter than the other.

No ſucceſsful attempt, as far as we have heard, was ever made to cultivate any of this genus; yet as gardeners now ſucceed with ſeveral of the *Orchideæ*, at one time thought quite as unmanageable, we know not why they ſhould deſpair, even of theſe paraſitical plants. Rotten ſtumps of fir, placed ſo as to receive their minute ſeeds, and then removed into a fit ſituation, might poſſibly attain the deſired end. S.

MONOU, in *Geography*, a country of Africa, north of the Grain coaſt.

MONOVAC, a town of Spain, in the province of Valencia; 21 miles W. of Alicant.

MONOULLAH, a town of Bengal; 12 miles N.W. of Goragot.

MON-PADRE, a town of the iſland of Margaretta.

MONPARA, a river on the weſt coaſt of the iſland of Borneo, which runs into the ſea, N. lat. 0° 36′. E. long. 109° 33′.

MONPAZIER, a town of France, in the department of the Dordogne, and chief place of a canton, in the diſtrict of Bergerac; 18 miles S.W. of Sarlat. The place contains 1028, and the canton 4691 inhabitants, on a territory of 245 kiliometres, in 14 communes. N. lat. 44° 40. E. long. 0° 59′.

MONPON, a town of France, in the department of the Dordogne, and chief place of a canton, in the diſtrict of Riberac. The place contains 1500, and the canton 5615 inhabitants, on a territory of 247½ kiliometres, in 10 communes.

MONQUEGNA, a juriſdiction of South America, in the dioceſe of Arequipa; about 40 leagues S. of the city of Arequipa, and 16 from the coaſt of the South ſea. This juriſdiction extends at leaſt 40 leagues in length, in an agreeable climate, adorned with large vineyards, from the produce of which great quantities of wine and brandy are made, which conſtitute its whole commerce. They ſupply all the provinces bordering on the Cordilleras, as far as Potoſi, by land carriage; while they are exported by ſea to Callao, where they are greatly valued. Here are alſo papas and olives. The principal town, which bears the ſame name, is inhabited by Spaniards, among whom are ſeveral noble and opulent families. S. lat. 17° 24′. W. long. 70° 56′.

MONREAL, a town of Spain, in Aragon; 23 miles W. of Calataiud.—Alſo, a town of Spain, in Navarre; 8 miles S.E. of Pamplona.

MONREALE, a town of Sicily, in the valley of Mazara, ſituated on a lofty hill; 3 miles W.S.W. of Palermo.

MONRO, Alexander, M.D., in *Biography*, an eminent anatomiſt, and the father of the medical ſchool of Edinburgh, was deſcended both by his paternal and maternal parents from diſtinguiſhed families in the north of Scotland. He was born in London, in September 1697, where his father, then a ſurgeon in the army of king William in Flanders, reſided upon leave of abſence in the winter. On quitting the army, Mr. Monro ſettled in Edinburgh; and perceiving early indications of talent in Alexander, his only child, he took great intereſt in ſuperintending his education. After having given him the beſt inſtruction which Edinburgh then afforded, he ſent him to London, where he attended the anatomical courſes of Cheſelden, and was extremely aſſiduous in diſſections: he made numerous anatomical preparations, which he ſent home; and, while here, even laid the foundation of his moſt important work on the bones, a ſketch of which he read before a ſociety of young phyſicians and ſurgeons, of which he had been elected a member. From London, Alexander went to Paris, where he purſued the ſame object; and in the autumn of 1718, repaired to Leyden, with the view of profiting by the tuition of the great Boerhaave, who conceived a high opinion of his talents and induſtry, and wrote a favourable account of him to his friends. On his return to Edinburgh, in the autumn of 1719, he was appointed profeſſor and demonſtrator of anatomy to the company of ſurgeons, the joint demonſtrators having ſpontaneouſly reſigned in his favour. Soon after accepting this appointment, he began alſo to give public lectures on anatomy, illuſtrating them by the preparations which he had made when abroad; and at the ſame time Dr. Alſton, then a young man, united with him in the plan, and began a courſe of lectures on the materia medica and botany. Theſe were the firſt public courſes that had ever been given at Edinburgh, and may be regarded as the opening of that medical ſchool, which has ſince extended its fame, not only throughout Europe, but over the new world. Mr. Monro ſuggeſted this plan; and by the following circumſtance, probably, contributed to lead his ſon into a mode of lecturing, which ſubſequently carried him to excellence. Without the young teacher's knowledge, he invited the preſident and fellows of the College of Phyſicians, and the whole company of ſurgeons, to honour the firſt day's lecture with their preſence. This unexpected company threw the doctor into ſuch confuſion, that he forgot the words of the diſcourſe, which he had written and committed to memory.

Having

Having left his papers at home, he was at a loſs for a little time what to do: but, with much preſence of mind, he immediately began to ſhew ſome of the anatomical preparations, in order to gain time for recollection; and very ſoon reſolved not to attempt to repeat the diſcourſe which he had prepared, but to expreſs himſelf in ſuch language as ſhould occur to him from the ſubject, which he was confident that he underſtood. The experiment ſucceeded: he delivered himſelf well, and gained great applauſe as a good and ready ſpeaker. Thus diſcovering his own ſtrength, he reſolved henceforth never to recite any written diſcourſe in teaching, and acquired a free and elegant ſtyle of delivering lectures.

In the ſame year, 1720, a regular ſeries of medical inſtruction was inſtituted at Edinburgh, through the intereſt of Dr. Monro's father: theſe two lectureſhips were put upon the univerſity eſtabliſhment, to which were ſoon after added thoſe of Drs. Sinclair, Rutherford, Innes, and Plummer. This ſyſtem of medical education was, however, incomplete, without affording ſome opportunity to the ſtudents of witneſſing the progreſs and treatment of diſeaſes, as well as of hearing lectures. A propoſal was, therefore, made to erect and endow an hoſpital by ſubſcription; and Dr. Monro publiſhed a pamphlet, explaining the advantages of ſuch an inſtitution. The royal infirmary was ſpeedily raiſed, endowed, and eſtabliſhed by charter; and the inſtitution of clinical lectures, which were commenced by Dr. Monro on the ſurgical caſes, and afterwards by Dr. Rutherford, in 1748, on the medical caſes, completed that admirable ſyſtem of inſtruction, upon which the reputation and uſefulneſs of the medical ſchool of Edinburgh have been ſubſequently founded.

None of the new profeſſors contributed ſo much to the celebrity of this ſchool as Dr. Monro, who was indefatigable in the labours of his office, and in the cultivation of his art, and ſoon made himſelf known to the profeſſional world by a variety of ingenious and valuable publications. During a period of nearly forty years he continued, without any interruption, to deliver a courſe of lectures, extending from the end of October to the beginning of May: and ſo great was the reputation which he acquired, both for himſelf and the univerſity, that ſtudents flocked to him from the moſt diſtant corners of the kingdom.

His firſt and principal publication was his "Oſteology, or Treatiſe on the Anatomy of the Bones," which appeared in 1726, and was intended for the uſe of his pupils; but it became a very popular work among the faculty in general: for he had the ſatisfaction of ſeeing it paſs through eight editions during his life, and it was tranſlated into moſt of the languages of Europe. The French edition, in folio, publiſhed by Mr. Sue, demonſtrator of ſculpture to the Royal Academy of Paris, was adorned with moſt elegant and maſterly figures. To the later editions of this work he ſubjoined a conciſe *neurology*, or deſcription of the nerves, and a very accurate account of the lacteal ſyſtem and thoracic duct.

Dr. Monro was alſo the father and active ſupporter of a ſociety, which was eſtabliſhed by the profeſſors and other practitioners of the town, for the purpoſe of collecting and publiſhing papers on profeſſional ſubjects, and to which the public is indebted for ſix volumes of "Medical Eſſays and Obſervations by a Society at Edinburgh," the firſt of which appeared in 1732. Dr. Monro was the ſecretary of this ſociety; and after the publication of the firſt volume, when the members of the ſociety became remiſs in their attendance, the whole labour of collection and publication was carried on by himſelf; "inſomuch that after this," ſays his biographer, "ſcarce any other member ever ſaw a paper of the five laſt volumes, except thoſe they were the authors of, till printed copies were ſent them by the bookſeller." Of this collection, many of the moſt valuable papers were written by Dr. Monro, on anatomical, phyſiological, and practical ſubjects: the moſt elaborate of theſe is an "Eſſay on the Nutrition of the Fœtus," in three diſſertations. Haller, ſpeaking of theſe volumes as highly valuable to the profeſſion, adds, "Monrous ibi eminet."

After the concluſion of this publication, the ſociety was revived, at the ſuggeſtion of the celebrated mathematical profeſſor, Colin Maclaurin, and was extended to the admiſſion of literary and philoſophical topics. Dr. Monro again took an active part in its proceedings, as one of its vice-preſidents, eſpecially after the death of Maclaurin, when two volumes of its memoirs, entitled "Eſſays Phyſical and Literary," were publiſhed, and ſome materials for a third collected, to which Dr. Monro contributed ſeveral uſeful papers. The third was not publiſhed during his life. His laſt publication was an "Account of the Succeſs of Inoculation in Scotland," written originally as an anſwer to ſome inquiries addreſſed to him from the committee of the faculty of phyſicians at Paris, appointed to inveſtigate the merits of the practice. It was afterwards publiſhed at the requeſt of ſome of his friends, and contributed to extend the practice in Scotland. Beſides the works which he publiſhed, he left ſeveral MSS. written at different times, of which the following are the principal; *viz.* A Hiſtory of Anatomical Writers;—An Encheireſis Anatomica;—Heads of many of his Lectures;—A Treatiſe on Comparative Anatomy;—A Treatiſe on Wounds and Tumours;—and, An Oration de Cuticula. This laſt, as well as the ſhort tract on comparative anatomy, has been printed in an edition of his whole works, in one volume, quarto, publiſhed by his ſon, Dr. Alexander Monro, at Edinburgh, in 1781. This tract had been publiſhed ſurreptitiouſly, in 1744, from notes taken at his lectures; but is here given in a more correct form.

In the year 1759, Dr. Monro reſigned his anatomical chair, which he had ſo long occupied with the higheſt reputation, to his ſon, juſt mentioned; but he ſtill continued to lecture as one of the clinical profeſſors on the caſes in the infirmary. His life was alſo a ſcene of continued activity in other affairs, as long as his health permitted. For he was not only a member, but a moſt aſſiduous attendant, of many ſocieties and inſtitutions for promoting literature, arts, ſciences, and manufactures in Scotland; he was alſo a director of the bank of Scotland, a juſtice of the peace, a commiſſioner of high roads, &c. and was punctual in the diſcharge of all his duties. His character in private life was as amiable and exemplary as it was uſeful in public. To the literary honours, which he attained at home, were added thoſe of a fellow of the Royal Society of London, and an honorary member of the Royal Academy of Surgery, at Paris.

Dr. Monro was a man of middle ſtature, muſcular, and poſſeſſed of great ſtrength and activity; but was ſubject for many years to a ſpitting of blood on catching the leaſt cold, and through his life to frequent inflammatory fevers. After an attack of the influenza, in 1762, he was afflicted with ſymptoms of a diſeaſe of a painful and tedious nature, which continued ever after, until it terminated his exiſtence. This was a fungous ulcer of the bladder and rectum, the diſtreſs of which he bore with great fortitude and reſignation, and died with perfect calmneſs, on the 10th of July, 1767, at the age of ſeventy.

Two of his fons became diftinguifhed phyficians. Dr. Alexander, his fucceffor, filled the anatomical chair with great credit to himfelf and to the univerfity, for upwards of forty years, and became known throughout Europe by his valuable publications; efpecially by his Treatife on the Lymphatics, in 1770;—On the Anatomy of Fifhes, 1785; —On the Nerves, 1783;—On the Burfæ Mucofæ, 1788; and three treatifes on the Brain, the Eye, and the Ear, in 1797. Advancing in years, and wifhing to relieve himfelf from the fatigues of the profefforfhip, he affociated with himfelf, in 1801, his fon, the third Alexander Monro, who now, 1812, continues to carry on the bufinefs of that chair with confiderable zeal and credit, while the refpected veteran fpends his age in repofe.

Dr. Donald Monro, the other fon of the firft Alexander, fettled as a phyfician in London, and attained confiderable eminence. He became known as the author of an Effay on the Dropfy, in 1765;—On the Difeafes of Military Hofpitals, 1764;—On Mineral Waters, 1771;—On preferving the Health of Soldiers; and fome other works, and died in the year 1802. See Life of Dr. Monro, prefixed to his works. Gen. Biog.

MONROE, in *Geography*, a county of Virginia, taken from Green Briar, on the fouth fide; 320 miles from Wafhington.

MONROYO, a town of Spain, in Aragon, on the frontiers of Catalonia and Valencia; 20 miles S. of Alcaniz.

MONS Veneris, in *Anatomy*, the elevation of the integuments over the pubes in the female fubject. See Generation.

Mons, in *Geography*, a town of France, and principal place of a diftrict, in the department of Jemmappe, or Gemmappe, of which it is the capital, fo called from its fituation on a hill. The river Trouide, which runs through it, joins the Haifne in its fauxbourg. Its caftle, which was demolifhed in 1618, is faid to have been built by Julius Cæfar, and Quintus Cicero, brother to the celebrated orator, was befieged in this place, and relieved by Cæfar, 50 years B.C. The town is large, the ftreets are broad, and the great market-place, which is very fpacious, contains the townhoufe, which is a fine old building, with a fteeple erected by the ftates in 1716, the palace of the government, and that of the council of the province. Thefe three palaces are adorned with fculpture and painting. The great church is a fine building, the fide altar and chapel being wholly conftructed of fine marble: here is a marble tomb, finely embellifhed; and the ftatues, among which are the four cardinal virtues, and the refurrection, are in high eftimation. Mons is a place of good trade for various articles, particularly woollen ftuffs, which are manufactured here in large quantities. The magiftracy is compofed of a chief, ten fchevins, two penfioners, three greffiers, &c. This town has frequently fuffered by the calamities of war. In 1746 its fortifications were demolifhed by the French; and in this ftate it was reftored to the emperor by the peace of Aix-la-Chapelle. After the battle of Jemmappe, it was fummoned by Dumourier, and furrendered the next morning. It contains 18,291 inhabitants, in 2 cantons; the north canton including 13,381, on a territory of $37\frac{1}{2}$ kiliometres, in 5 communes; and the fouth containing 14,252, on a territory of 45 kiliometres, in 8 communes. N. lat. 50° 27′ 10″. E. long. 3° 37′ 15″.

MONSEFU, a town of Peru, in the bifhopric of Truxillo; 12 miles S. of Lambayeque.

MONSEIGNEUR, compounded of *mon, my,* and *feigneur, lord,* in the plural meffeigneurs, a title of honour and refpect ufed by the French in writing to perfons of fuperior rank or quality.

Dukes, peers, archbifhops, bifhops, and prefidents *a la mortier*, are complimented with the title of monfeigneur.

In the petitions prefented to the fovereign courts, they ufe the term meffeigneurs.

Monseigneur, abfolutely ufed, was a title formerly reftrained to the dauphin of France.

This cuftom was unknown till the times of Louis XIV., till then the dauphin was ftyled monfieur le dauphin.

MONSIEUR, a compound of *mon, my,* and *fieur, fir,* in the plural meffieurs, a term or title of civility, ufed by the French, in fpeaking to their equals, or thofe a little below them; anfwering to Mr. or Sir, among the Englifh.

The fuperfcription of all letters begin *A monfieur, monfieur* fuch a one.

The ufe of the word monfieur was formerly more extenfive than at prefent: they applied it to people who lived many ages before them. Thus monfieur St. Auguftine, monfieur St. Ambrofe; and the vulgar ftill fay, monfieur St. Paul, monfieur St. Jaques, &c. The Romans, during the flourifhing time of their liberty, were unacquainted with that term of parade and flattery, which they afterwards made ufe of in the word *dominus*. In fpeaking or writing to each other, they only gave each other their proper names; which practice lafted even after Cæfar had brought the republic under his command: but after the Roman emperors were once well feated on the throne, the courtiers and minions, who by flattery fought to procure favours from them, ftudied new honours. Suetonius obferves, that a comedian on the theatre having called Auguftus *dominus, lord;* the fpectators all ftared at him; fo that the emperor forbad, for the future, the title to be attributed to him. Caligula was the firft who exprefsly commanded himfelf to be called *dominus*. Martial, entirely devoted to tyranny, calls Domitian *dominum deumque noftrum*. In time, the title was alfo applied to the people; and of *dominus*, at length was formed *dom*.

Monsieur, abfolutely ufed, is a title or quality formerly appropriated to the fecond fon of France, or the king's brother.

In a letter of Philip De Valois, that prince, fpeaking of his predeceffor, calls him *monfieur le roy*, monfieur the king.

MONSIGNI, M. de, in *Biography*, formerly maitre d'hotel to the duke of Orleans, father of l'Egalité, was one of the creators of the French comic opera, for which, between the years 1759 and 1777, he compofed eleven or twelve different dramas, which, we believe, were all fuccefsful; particularly "Le Cadé Dupé; on ne s'avife jamais de tout;" "Le Roi et le Fermier;" "Rofe et Colas, &c."

This kind of drama was eftablifhed at the theatre de la Foire, in 1754, upon the idea of the Italian burletta, in all things except the recitative, the dialogue in the French opera comique being fpoken, and incidentally mixed with airs. This ingenious and pleafing compofer's name of Monfigni feems Italian; but his ftyle of melody is neither Italian nor French, but a mixture of both. Nothing could be more pleafing and amufing than thefe dramas to the natives of all Europe, not great critics in finging; for it muft be owned, that they were all well written, well fet, and well acted; and in the principal man's part, when performed by the admirable Caillot, well fung. Duni, Philidor, and Monfigni, were the patriarchs of the comic mufical dramas, and Gretry the king David.

MONSOL,

MONSOL, in *Geography*, a town of Africa, in the kingdom of Anziko, and residence of the micocco or king. S. lat. 1°. E. long. 3° 50'.

MONSON, *Sir* WILLIAM, in *Biography*, a naval commander, and a writer upon naval subjects, was born about the year 1569, and was sent, at an early age, to Baliol college, Oxford, where he remained about two years. Being desirous of engaging in the sea-service, to which, probably, his parents objected, he entered, without their knowledge, on board a small vessel, fitted out to cruise against the Spaniards. After some years' active service, he accompanied the earl of Cumberland in two expeditions, in the second of which he was taken by the Spaniards, and was detained a prisoner two years. As soon as he was liberated, in 1593, he attached himself again to the earl's service, in which he made two more voyages. In 1596, he was captain of a ship in the earl of Essex's expedition to Cadiz, and in the next year in that to the Azores. After the accession of king James, he was appointed, in 1604, admiral of the narrow seas, an office which he sustained twelve years with credit to his own well earned reputation, and honour to the British flag, by protecting the trade and fisheries from all encroachments. His zeal against the pretensions of the Dutch, and his endeavours to promote an enquiry into the state of the navy, against the will of the earl of Nottingham, lord high admiral, involved him in troubles, and occasioned his committal to the Tower, in 1616; but upon examination into his conduct he was discharged. He was consulted on the duke of Buckingham's expedition against Algiers, Cadiz, and the isle of Rhé, all which he disapproved, and his opinion was fully justified by their want of success. To his country his opposition was unavailing, and to him it was unfortunate, having been kept out of employ for several years; but in 1635 he was appointed vice-admiral. After this he withdrew to a life of privacy, and employed himself in finishing his "Naval Tracts." He died in February, 1642-3, leaving a high reputation as a brave, prudent, and upright commander. He had not the good fortune to perform any very splendid services, yet his zeal for the improvement of the navy of his country merits an honourable mention. His Naval Tracts contain plans and projects for the advancement of the interests of trade and navigation. They are inserted in the third volume of Churchill's Collection of Voyages. Biog. Brit. Campbell's Lives of the Admirals, Stockdale's edition.

MONSON, in *Geography*, a township of Hampshire county, Massachusetts, E. of Brimfield.

MONSONIA, in *Botany*, is designed to commemorate the late lady Ann Monson, a lady of distinguished talents, as well as of eminent botanical taste and knowledge, who by a long residence in the East Indies, had great opportunities of cultivating the study of plants, as well as insects. We trust we shall betray no inviolable secret, in recording that it was to this excellent lady the late Mr. Lee alluded, in the preface to his Introduction to Botany, first published in 1760, where he says he was enjoined not to acknowledge his obligations to those who had kindly helped him in his undertaking. A most elegant East Indian *Illecebrum* was first chosen by Koenig, if we mistake not, to bear the name of *Monsonia*, which remains as its specific appellation; and a more distinct genus, of greater splendour, has been selected for the purpose. Some have thought this but too near to *Geranium*.—Linn. Mant. 14. Schreb. 459. Willd. Sp. Pl. v. 3. 717. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 100. Juss. 269. Lamarck Illustr. t. 638. Cavan. Diss. 179.—Class and order, *Polyadelphia Dodecandria*. Nat. Ord. *Gruinales*, Linn. *Gerania*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, awned, equal, permanent leaves. *Cor.* Petals five, obovate, abruptly toothed, and jagged, longer than the calyx, inserted into the short annular receptacle, or nectary. *Stam.* Filaments fifteen, united into five sets, three in each set, all inserted into the nectary; anthers oblong. *Pist.* Germen superior, pentagonal, short; style awl-shaped; stigmas five, oblong, spreading. *Peric.* Capsules five, aggregate, cartilaginous, oblong, lateral, separating at their inside, each attached upwards to a very long, spiral, elastic awn. *Seeds* solitary, lateral, oblong, somewhat cylindrical.

Eff. Ch. Calyx of five leaves. Petals five, abrupt, toothed. Stamens in five sets, united by a common base. Style five-cleft. Fruit beaked, of five aggregate capsules, with long spiral awns.

1. M. *speciosa*. Large-flowered Monsonia. Linn. Mant. 105. Curt. Mag. t. 73. Cavan. Diss. 179. t. 74. f. 1.—Leaves quinate; leaflets bipinnatifid.—Native of the Cape of Good Hope, like the whole genus. It was sent to Kew in 1774, by Mr. Masson, and decorates the green-house magnificently in spring. *Root* perennial. *Stems* sometimes very short. *Leaves* numerous, mostly radical, on long stalks, and composed of five radiating hairy leaflets, doubly pinnatifid; their segments linear-lanceolate, bluntish, decurrent. *Flowers* two or three inches broad, with deeply cut petals, variegated with shades of rose-colour, ribbed, the eye purple and white; each on a long, bent, simple *stalk*, with a whorl of lanceolate *bracteas* at its joint. *Calyx-leaves* membranous at the edge, downy upward. Beak of the *fruit* three inches long, its awns hairy at the inside.

2. M. *lobata*. Broad-leaved Monsonia. Dryand. in Ait. Hort. Kew. ed. 1. v. 3. 100. Willd. n. 3. (M. filia; Linn. Suppl. 341. Cavan. Diss. 180. t. 74. f. 2. Andr. Repos. t. 276.)—Leaves heart-shaped, deeply lobed, toothed.—Differs from the last in having the *leaves* lobed, not compound, though they are sometimes so deeply cut as almost to approach the former. In the *flowers* there is scarcely a permanent distinction. The *petals* of the present species are usually greenish at the back, white, with a tinge of red, above. It is much to be suspected that these are but varieties of each other.

3. M. *ovata*. Undulated Monsonia. Willd. n. 4. Cavan. Diss. 193. t. 113. f. 1. (M. emarginata; L'Herit. Geran. t. 41. Geranium emarginatum; Linn. Suppl. 306.)—Leaves ovate-oblong, toothed, plaited; somewhat heart-shaped at the base.—Sent from the Cape to Kew garden, in 1774, by Mr. Masson, with both the former. This is more caulescent than those, but more slender, and only a biennial. The *leaves* are nearly ovate, about an inch long. *Flowers* pale yellow, about an inch in diameter. Beak of the *fruit* two inches in length. The *branches*, *flower-stalks*, and *calyx* are clothed with very long spreading hairs.

4. M. *spinosa*. Thorny Monsonia. Willd. n. 5. L'Herit. Geran. t. 42.—Leaves elliptical, pointed, entire. Footstalks permanent, hardening into thorns.—*Stem* shrubby, branched, beset with thorns, which are the hardened *footstalks* of former leaves. *Flowers* larger than in the last.

M. *tenuifolia*, Willdenow's first species, is our *Grielum tenuifolium*. See GRIELUM.

MONSONIA, in *Gardening*, contains plants of the herbaceous under-shrubby biennial and perennial kinds, for the green-house, of which the species cultivated are, the fine-leaved monsonia (M. speciosa); the broad-leaved monsonia, (M. lobata); the undulated monsonia (M. ovata.)

Method of Culture.—The first sort, as it rarely if ever ripens seeds in this climate, must be increased by cuttings of the

the root, which ſhould be planted in pots of good mould, and plunged in a tan hot-bed, watering them occaſionally, when in a little time buds appear on the tops of the cuttings which are left out of the ground. They ſhould be treated as hardy green-houſe plants, or be afterwards removed into ſeparate pots, and ſheltered under a good garden-frame in the winter ſeaſon. And the ſecond ſort may be beſt raiſed in the ſame manner.

But the third ſort ſhould be raiſed from ſeeds, which muſt be ſown in the early ſpring, in pots of light earth, and plunged in a mild hot-bed. When the plants are come up, they ſhould be removed into other pots ſeparately and be managed as the other kinds.

Theſe afford variety among other potted plants.

MONSOON, a regular or periodical wind in the Eaſt Indies, blowing conſtantly the ſame way, during ſix months of the year, and the contrary way the remaining ſix.

In the Indian ocean, the winds are partly *general*, and blow all the year round the ſame way, as in the Ethiopic ocean; and partly *periodical*, *i. e.* half the year blow one way, and the other half year on the oppoſite points: and thoſe points and times of ſhifting differ in different parts of this ocean. Theſe latter are what we call monſoons.

The ſhifting of theſe monſoons is not all at once: and in ſome places the time of the change is attended with calms, in others with variable winds, and particularly thoſe of China, at ceaſing to be weſterly, are very ſubject to be tempeſtuous: and ſuch is their violence, that they ſeem to be of the nature of the Weſt India hurricanes, and render the navigation of thoſe ſeas very unſafe at that time of the year. Theſe tempeſts the ſeamen call the *breaking up of the monſoons*.

Monſoons, then, are a ſpecies of what we otherwiſe call *trade-winds*.

They take the denomination monſoon from an ancient pilot, who firſt croſſed the Indian ſea by means of it. Though others derive the name from a Portugueſe word ſignifying *motion*, or change of wind, and ſea.

Lucretius and Apollonius make mention of annual winds which ariſe every year, *eteſia flabria*, which ſeem to be the ſame with what in the Eaſt Indies we now call monſoons. For the phyſical cauſe of theſe winds, ſee METEOROLOGY and WIND.
